Th[illegible] Goulstonian Lectures

ON

INFL[illegible] OF PREGNANCY UPON TAIN M[illegible]AL DISEASES AND OF CERTAIN MEDICAL DISEASES UPON PREGNANCY.

d before the Royal College of Physicians of London on March 17th, 19th, and 24th, 1908,

HERBERT FRENCH, M.A., M.D. OXON.,
F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO GUY'S HOSPITAL.

257

LECTURE I.

Delivered on March 17th

INTRODUCTION.

PRESIDENT AND GENTLEMEN,—The title of these s perhaps requires a few words of explanation in might be at all misleading. The subjects that it is ed to discuss will not be dealt with from an rical point of view, but purely from their medical or ogical aspect. The gynæcologist and the obstetrician naturally be interested in the medical diseases which rise in a pregnant woman, and in some cases the ent in these circumstances may be gynæcological stetrical rather than medical. I have not the to deal with gynæcological or obstetrical treatment, hall therefore say nothing about it. On the other the fact that a medical disease arises, or is already t, when a patient has become pregnant by no necessarily implies that the immediate treatment patient should be carried out from a gynæcological or rical standpoint. It is true that there are conditions which the aid of the obstetric physician may be ed to terminate the pregnancy artificially, and it is rue that similar aid will be essential when the pregnancy es its natural term, or earlier if any accidental termina- o it should arise. There are, however, many conditions ich the pregnancy may be, as it were, an accidental mitant or complication of the medical disease; there her conditions in which pregnancy is actually the cause medical disease, and many of these cases are of direct st to the physician.

n a given case it should be decided that the pregnancy be allowed to run its natural course, the responsibility patient's health would rest with the physician until as the pregnancy either reached its term or ceased self normal. It is, therefore, essential that the ian should be fully acquainted with the probable s both of the pregnancy upon the medical disease from h the patient may be suffering and also of the medical se upon the pregnancy. Two examples may perhaps this explanation. Suppose, for instance, that a pregnant an contracts typhoid fever. Three questions at once arise mely, Is the fact that this patient is pregnant likely ake the typhoid fever more severe than it otherwise ld be? Is the patient's pregnancy likely to terminate rmally on account of the typhoid fever? Ought the tment of this patient to be different in any way from of other persons suffering from typhoid fever? It is that, so far at least as the typhoid fever is concerned, treatment should be carried out by those most familiar typhoid fever if it can be shown that the treatment of cases ought to be upon the same lines as that of non- nant persons suffering from the disease. So far as the hoid fever is concerned the pregnancy may be an idental concomitant, but it is important to the physician now what is likely to be the result of the combination.

s my second example, may I take that of a patient who ents herself with that peculiar skin eruption, herpes tationis? If she were not pregnant she would not have the ption; but having the eruption the immediate treatment the patient for her skin trouble is probably best carried by one who is most familiar with skin diseases, provided is known that the pregnancy is not likely to run an normal course.

It is only from the medical point of view that I am in a position to discuss the mutual effects of pregnancy and medical diseases; and seeing that there are few medical diseases that cannot either themselves arise during pregnancy or else permit of pregnancy occurring when they are already in existence, it is clear that the whole field cannot be covered in three lectures. I am obliged therefore to restrict the discussion to a few affections which appear to possess particular interest.

In the first place, there are certain medical diseases for which pregnancy appears to be itself directly responsible. One of the most definite of these, comparatively rare no doubt, yet full of interest from a pathological point of view, is

HERPES GESTATIONIS.

This disease is apparently related to pemphigus, to hydroa, to erythema bullosum, and to dermatitis herpetiformis or Dühring's disease. The eruption is variable in the extent to which erythematous patches, pinkish-red papules, and wheals not unlike those of urticaria are present, but to whatever degree these may coexist the distinctive lesion is vesicular or bullous. Sometimes the blebs are comparatively large and widely separated and they are preceded by more or less erythema, in which case the eruption is very similar to that of erythema bullosum. More rarely the bullæ occur before any erythema is obvious and pemphigus is simulated. In other cases again the vesicles are smaller and they may be arranged in groups upon an inflamed base like those of herpes zoster—the herpetiform variety. The cases that I have seen have exhibited a mixed condition, the majority of the vesicles being only moderate in size, with here and there amongst them a few that were large enough to be called bullæ; the smaller vesicles have shown a slight tendency to be grouped together as in herpes, but it is not often that they are confluent or that a single group contains as many vesicles crowded together as is the case in well-marked herpes zoster. The vesicles, whether large or small, have been preceded by an itching erythema which has in the beginning been smooth but which has rapidly become first papular and then vesicular. The eruption itself has been more like that of dermatitis herpetiformis than anything else, the chief clinical distinction between the two being solely the direct relationship of herpes gestationis to pregnancy.

An illustrative case.[1]—The following is an illustrative case. The patient, 41 years of age, was under the care of Sir Cooper Perry in Guy's Hospital, and was sufficiently ill to require treatment in bed for over a month. Her history was briefly this: She was the only member of her family troubled with the complaint. She had been perfectly well up to, and for some time after, her marriage, when she was 23 years old. She had had seven living children and four miscarriages. The first miscarriage occurred after she had had three living children and it was then that she suffered from her skin trouble for the first time. Since then, though quite free from it between whiles, she had had the eruption with each successive pregnancy, the itching erythema, vesicles, and bullæ recurring constantly upon her hands and arms and sometimes upon her trunk, legs, and feet. She was three months' pregnant at the time of her admission to the hospital; one month previously her ninth attack of herpes gestationis began with pains and irritation on the hands and forearms, rapidly followed by the eruption of discrete water-blisters of moderate size which, owing to scratching, broke down and discharged clear fluid. Each bleb dried up and healed in about a week, leaving a reddish mark which was slow to fade, whilst fresh vesicles kept on appearing daily in the neighbourhood. There was no pyrexia and no marked constitutional disturbance beyond what could be attributed to broken sleep, the result of irritation in the affected areas of skin. The arms and hands had been involved for three weeks before vesicles developed elsewhere, and then without apparent cause a precisely similar eruption came out upon the face and ears, spreading thence to the chest, abdomen, buttocks, lower limbs, and feet. The number of blebs upon the trunk was never so great as that upon the limbs. Flexor and extensor surfaces were equally involved and the parts were not only irritable but also painful. The pains were doubtless due, in part at least, to the sore places being made worse by scratching. Left to themselves the blebs healed without breach of surface and without pyodermia. Some of the vesicles that had been interfered with either bled or became pustular; the latter change was always consequent upon inoculation by scratching. There was no involvement of mucous membranes, though there are doubtless cases in which the buccal mucosa and the colon may be affected, as has been observed in some instances of erythema bullosum. Under treatment by the yellow oxide of mercury ointment externally and by Fowler's solution of arsenic internally, together with rest in bed, light diet, and laxatives, there was some abatement in the skin trouble after about three weeks, but even during the continuance of the treatment a severe relapse ensued whilst the patient was still in the hospital. The trouble, waxing and waning in this way, persisted until the child was born, living, at term, and then, as on eight former occasions, the herpes gestationis rapidly got well by itself.

---

[1] See also C. A. Douglas Bryan, THE LANCET, June 4th, 1904, p. 1570, and numerous papers in the journals of dermatology.

This case is fairly typical, and there are but few points to add before passing on to consider the pathology of the condition. It is not only possible for a patient like the above to have no trouble during the first pregnancies and then to develop the disease in later ones, but it is also possible that having had the skin disease in one pregnancy she may escape it at the next and yet develop it again in a later one. The time of onset is usually of the accelerating type, that is to say, in successive pregnancies it is likely that the date at which the herpes gestationis will reappear is a little earlier each time. It is, moreover, probable that the attacks will tend to become severer rather than the reverse. A few cases exhibit severe constitutional disturbance, with pyrexia and loss of appetite. It is, moreover, a curious fact that whereas the majority of the patients develop the trouble during pregnancy and lose it during the puerperium or soon after, it occasionally happens, as in another case under the care of Sir Cooper Perry, that the eruption first appears after labour, lasts a variable number of weeks or months, and then goes away spontaneously not to reappear until just after another child has been born.[2]

Pigmentation.—Another point that may be of interest perhaps is the increased pigmentation of the skin that is apt to be left after each attack. The pigmentation may be generalised all over the body in much the same way as it is in severe cases of Addison's disease. Usually, however, it is most marked in those parts of the skin in which the eruption itself has been worst. It is well known that uterine disorders are apt to cause pigmentation—the uterine chloasma—but this is, as a rule, much more marked upon the face, especially upon the forehead and around the eyes, than it is elsewhere. There is little or no evidence that the pigmentation which follows herpes gestationis is in any way allied to uterine chloasma; indeed, there is seldom any obvious uterine derangement in the patients who suffer from it. The chief causes of the pigmentation are probably, first, the constant scratching or rubbing that the irritation in the affected parts gives rise to, just as it does in phtheiriasis, where pigmentation also becomes well marked as time goes on; and secondly, the arsenic which is administered in most of the cases. The darkening of the skin is so great in some patients that they look as if they might be of coloured extraction. There is apparently no record as to whether or not the pigmentation ever occurs upon the buccal mucosa as well as upon the skin, but between the attacks of herpes gestationis it would sometimes not be difficult to mistake the general appearance for that of Addison's disease if the history of the skin trouble were concealed.

Pathology.—The direct relationship of the disease to pregnancy is very remarkable. It seems to be the only point distinguishing it from dermatitis herpetiformis. I should like in this connexion to say a few words about eosinophilia.

Eosinophilia.—It is often stated in a general way that eosinophilia occurs in a large number of skin diseases. To test this I have made differential leucocyte counts in a number of all kinds of eruptions, and in the great majority of the commoner varieties there is no eosinophilia at all.[3] If it be granted that nothing less than 5 per cent. of coarsely granular eosinophile cells in the blood can be termed eosinophilia, it is quite exceptional for cases of eczema, psoriasis, and the like to exhibit it. The reverse is true of the bullous dermatoses, however. There are, of course, a good many cases of pemphigus in which no eosinophilia is found at a single examination, and the percentage of coarsely granular eosinophile corpuscles varies not only in different individuals suffering from the same disease but also in the same in viduals at different times. Nevertheless, in patients sufferi from pemphigus or from dermatitis herpetiformis, eosinophil is the rule rather than the exception, as Bettmann, Darie and others have pointed out. The degree of eosinophilia i the blood is moderate rather than great, the coarsely granula eosinophile corpuscles numbering something between 5 pe cent. and 15 per cent. of all the leucocytes in typical cases.

It is worthy of note that the eosinophilia is not in th blood alone, but that the eosinophile corpuscles are als present in the inter-epithelial lymphatic spaces, where the may be seen in the microscopical sections of the skin; and further, that in the fluid of the blebs themselves there ar leucocytes, of which over 70 per cent. may be of th eosinophile variety. It is recorded as a curious fac that, although the fluid in the natural blebs contain so large a preponderance of eosinophile cells, there is n such preponderance of these corpuscles in the fluid of a artificial blister made upon the patient's skin, by can tharides for example.

Herpes gestationis agrees with the other bullous dermatoses in exhibiting eosinophilia. The differential leucocyte count in the case mentioned above was as follows: Small lymphocytes, 11 per cent.; large hyaline lymphocytes, 4 per cent.; polymorphonuclear cells, 71 per cent.; and coarsely granular eosinophile cells, 14 per cent. The significance of the eosinophilia is obscure. There are, of course, three main groups of conditions in which eosinophilia occurs. These are: First, those parasitic affections in which there is constitutional disturbance, notably in patients suffering from ankylostomum duodenale, trichina spiralis, filaria sanguinis hominis, bilharzia hæmatobia, hydatids, and sometimes with tæniæ and scabies, but not with the milder parasitic affections such as those of trichocephalus dispar, oxyuris vermicularis, ascaris lumbricoides, or tinea tonsurans and allied trichophytic affections. Secondly, true spasmodic asthma, in which eosinophilia is found during the attacks but not between them. Thirdly, certain skin diseases, chiefly the bullous dermatoses, as mentioned above. It is difficult to say why eosinophilia should be a prominent feature in these three groups of conditions and not in a great many other affections. It is thought that a poison of some kind is at the bottom of it in the parasitic diseases; that a toxin can produce a local eosinophilia was shown in the Johns Hopkins Hospital where the vascular spaces around appendicular abscesses were demonstrated to be full of eosinophile corpuscles although there was no excess of eosinophile cells in the general circulation. True asthma, however, is usually regarded as primarily a nervous phenomenon, and it is not at all clear why it should be associated with eosinophilia. It may be that there is an unknown poison which starts the neuro-muscular spasm in the bronchioles; otherwise it would seem that eosinophilia may have a nervous as well as a toxic origin.

The eosinophilia of skin diseases has been so little studied that it does not seem to be known whether the blood contains the excess of eosinophile cells before the eruption comes out or whether the bullæ always precede the eosinophilia. If the former were the case, then both the eosinophilia and the vesicles would probably have a common cause, whether that were nervous or toxic. The general opinion is, however, that the eosinophilia *is* the result of the skin lesion, due perhaps to the absorption of something from the skin in a way that would be comparable to the eosinophilia of ankylostomiasis, where there is supposed to be absorption of some toxin from the bowel. This raises the question of the pathology of the bullous dermatoses in general and of herpes gestationis in particular. It seems fairly clear that their causes arise within the body and that the lesions are not due to agents acting directly upon the skin from without. Bacteriological investigations have proved negative, the only micro-organisms that have been cultivated from the blebs being such as are readily explained as derived from accidental contamination from the skin.

Histology.—The actual process by which the vesicle o bulla develops seems to be as follows. There is a local dilatation of the papillary and sub-papillary blood-vessels and an almost simultaneous increase in the quantity of lymph in the spaces around the prickle-cells of the epidermis. The local erythema is caused by the vascular dilatation and the itching is doubtless due to the tension put upon the cutaneous nerve endings by the sudden increase in the quantity of pericellular lymph. There is no proliferation of the cells themselves, such as occurs in eczema, though leucocytes may accumulate in the part by diapedesis. The pericellular lymph goes on increasing in quantity until the protoplasmic bridges between the prickle-cells are mechanically torn asunder; larger and larger numbers of dilated intercellular spaces in this way become united into a single cavity and a vesicle results. If the lymphatic dilatation is spread uniformly over a comparatively wide area, a single large bulla is formed; if within the same area the dilatation is irregularly distributed with several maximum points, a group of smaller vesicles is produced; if the original area of vascular dilatation is small, a single vesicle, too small to be termed a bulla, results. The size of the bleb is therefore to some extent an accident. The depth at which the vesicles form is also more or less accidental; in some cases the fluid accumulates quite close beneath the stratum corneum; in others, so deeply that only the papillary layer separates it from the corium. The transitional layer is the level at which the lymph is able to separate the cells with greatest ease, so that it is here that the vesicle or bulla originates most commonly. The surrounding prickle-cells swell up, become more or less spherical, and assume an appearance which led Professor Unna to term them "balloon cells." Notwithstanding their altered appearance, they still retain their nuclei and their vitality for a long while, though many of them ultimately become more and more swollen and homogeneous, and finally break up.

---

[3] Herbert French: Eosinophilia in Skin Diseases, Guy's Hospital Reports, 1903.

Allied conditions.[4]—It would not, I think, be surprising if the degree of lymph accumulation between the prickle-cells sometimes stopped short of vesicle formation. Local patches of erythema, accompanied by much itching and even pain, would then be the only features of the disease, and, as Sir Cooper Perry has pointed out to me, there are not a few cases in which women during each successive pregnancy suffer from skin trouble of this kind. The characters of the lesion are then such as lead to a diagnosis of pruritus or urticaria, as the case may be. The relationship between urticaria and vesicular or bullous eruptions is well seen in young children. Infants have so tender a skin that ordinary urticaria in them not infrequently ends in the production of vesicles. Some of the cases of pruritus or urticaria of pregnancy are very probably examples of abortive or incomplete herpes gestationis. It would be very interesting to know whether or not there is eosinophilia in these patients too, but I have not yet been able to make any investigations upon this point.

The changes described above suggest that the trouble arises from there being something the matter within the vessels themselves. It would seem that the trouble is either primarily nervous or else that there is some poison circulating within the vessels at the time. The generally accepted view appears to be that the disease is primarily nervous, in which case it would be analogous to herpes zoster, or more correctly perhaps with factitious urticaria, or with angeioneurotic œdema. On the other hand, by analogy with the urticaria which sometimes follows the ingestion of certain foods, or with the vesicular or pustular eruptions that may follow the administration of certain drugs, such as the bromide or the iodide of potassium, it is at least quite as likely that there is a toxic agent or poison concerned in herpes gestationis. If the disease were purely the result of an angeioneurosis it would seem surprising that the eruption should so often be restricted entirely to the times of pregnancy. It is true that cases have been recorded in which the attacks came on apart from, as well as during, pregnancy, but this is distinctly unusual, and such cases would be termed true dermatitis herpetiformis rather than the distinct variety we are now speaking of. Pregnancy seems to be an essential cause of the latter. The patients are not necessarily of nervous disposition; the lady whose case has been given above was a most sensible woman; there was no history of nervous disorder in her family, nor of nervous shock nor of anything of that kind in herself. Moreover, one cannot trace any hereditary tendency to the disease, such as is well known in cases of angeioneurotic œdema. It is not at present possible to bring forward any conclusive arguments, however, one way or the other as to whether herpes gestationis is primarily nervous or primarily toxic in origin. No toxin is known, but this does not prove that none is present. It is even possible that no abnormal substance is present in these cases at all, but that the patients are unduly susceptible to some compound which is a normal metabolic product of the pregnant state. The idiosyncrasy of some persons in regard to strawberries might be used as a comparison. Most people can partake of this fruit in moderation with impunity, but a few cannot eat a single strawberry without suffering acutely from urticaria.

The pregnancy itself is not interfered with by the skin disease provided that suitable treatment is adopted to prevent pyodermia and to enable the patient to get a sufficiency of sleep. The children are born living and healthy, and it seems that the offspring of a mother who has been subject to the complaint are not particularly liable to any of the bullous dermatoses, nor are the females more liable than others to herpes gestationis. It is, however, very difficult to obtain direct evidence on this point, because few physicians see any large number of the cases and fewer still are likely to pay particular attention to the point in question.

This may, perhaps, be a good opportunity for mentioning a subject which Dr. Lauriston E. Shaw has spoken to me about sometimes—namely, that of the necessity for collective investigations being made upon special clinical and pathological points of this kind. There are many questions which, owing to the smallness of the number of cases that any individual is likely to see, can only be elucidated by collective inquiry. The Clinical Society, the Royal Medical and Chirurgical Society, and other similar bodies have from time to time instituted inquiries of the kind, but for the most part the data have been collected *after* the cases have been seen—from ward reports, post mortem records, and so forth. The very points upon which one wishes information are often not referred to at all in these, simply because the student or other person who wrote the report had not the knowledge or the interest to make a note about it. There are many conditions in which those who, having made a study of the cases up to a certain point, and having come across difficulties upon which they can nowhere find fuller information, could advise others as to special points to be upon the watch for and to pay particular attention to in *future* cases as they come under observation. The selection of the questions that might seem suitable for collective investigation in this way must necessarily lie with those who already know much. Dr. Mahomed when he was alive initiated a system of the kind but it died with him. The anatomists have a list of points upon which collective investigation is required, and in the dissecting room at Oxford there was a book in which were entered certain features of the anatomy of the vermiform appendix in each cadaver that was dissected, in order that by the accumulation of these and of a similar series of records from various other dissecting rooms certain debated points as to this particular part of anatomy might finally be settled. Some similar scheme might be possible as an assistance in settling debated points in medicine a few at a time. It would require a central authority for the selection of the points to be investigated, and the collaboration of all physicians at all hospitals would need to be sought. The central authority would doubtless be a permanent committee of physicians, and if the scheme were feasible at all the selection of such a committee for the direction of collective inquiry into obscure or debatable points in medicine and pathology would best, perhaps, be made under the auspices of either the Association of Physicians of Great Britain and Ireland or else of the Royal Society of Medicine of London. If Dr. Shaw's suggestion commends itself to others it should not be a difficult matter for a beginning to be made.

One might be asked, for example, whether an unmarried lady who had suffered from severe dermatitis herpetiformis previously to marriage would be likely to have still worse attacks of this disease should she marry and become pregnant. There are, so far as can be ascertained, no statistics to help one to answer such a query, important though it might be in some particular case. The general impression that is left upon one's mind after seeing a few cases and reading of as many more as one can find is that dermatitis herpetiformis and herpes gestationis, though in many respects so similar to one another, are yet sufficiently different to warrant the statement that pregnancy is by no means likely to bring on an attack of the former, though almost certain to cause a repetition of the latter. Again, one might be asked whether a patient who has suffered from dermatitis herpetiformis before marriage or from herpes gestationis after marriage would be likely to transmit the tendency to either disease to her children. As has been mentioned, one's general impression is that there is no beginning at the bladder itself, but just above the bladder about the level of the pelvic brim. The second is the fact that the inflammation is not confined to the pelvis of the kidney in these cases, but extends right up into the cortex, as was demonstrated at the operation. And the third is that notwithstanding the existence of large numbers of small abscesses in a kidney affected by an extreme degree of suppurative pyelonephritis of this kind, uræmia in the ordinary sense need not supervene and the patient may recover completely. No doubt it depends to some extent upon the nature of the organism present whether recovery is likely to occur or not, and in these cases it is always, or nearly always, the bacillus coli communis. This organism, however, is usually accredited with particular virulence when it affects parts outside the alimentary canal; and if the miliary abscesses had not been ocularly demonstrated at the operation it would have been difficult, in view of the subsequent complete recovery, to have believed that such abscesses had actually been present. One wonders whether it is as true as it is usually held to be that multiple abscesses in another organ—namely, the liver in suppurative pylephlebitis—must necessarily be fatal also. In view of these multiple abscesses in the kidney getting well it would seem possible, if not probable, that similar multiple abscesses in the liver may get well too sometimes.

---

The pathology of the pyelonephritis.—Turning now to the pathology of the pyelonephritis of pregnancy there are certain points that are fairly clear. The cases that have been collected by Mr. Bellingham Smith and others all indicate that previously to the pregnancy there was no renal trouble. It is probable, therefore, that the gravid uterus is a responsible factor in the production of the mischief. It is also clear that the pyelonephritis is not secondary to cystitis, for in practically all the patients the bladder has been healthy, at any rate at the beginning of the disease. Further, it has been demonstrated at the necropsy in some cases, and at operation in others, that there is dilatation of the ureter, beginning about an inch above the bladder. Putting all these facts together it seems almost certain that the sequence of events is: enlargment of the uterus; compression of the ureter against the brim of the true pelvis; consequent difficulty in the ejection of urine secreted by the corresponding kidney; infection of the urine retained in the partially obstructed ureter and renal pelvis; and subsequent spread to the kidney substance itself. The pyelonephritis of pregnancy would thus be comparable in some respects with pyelonephritis due to other causes, such as enlargement of the prostate in man; and just as in the latter case removal of the obstruction tends to cure the renal mischief, so does the birth of the child result in most cases in rapid amelioration and even complete cure of the trouble from which the pregnant woman has suffered.

It is a curious but very definite fact that in nearly every case the right kidney is very much more affected than is the left. In both the patients of whom notes have been given this was so. It is probable that the left kidney does not escape entirely, and indeed there is usually some pain in the left loin as well as in the right, but in the majority of cases the symptoms indicate that the mischief is mainly on the right side. There have been several explanations offered to account for this; perhaps the best is that of Cumston. He states that whilst the pregnant uterus develops its borders come nearer to the ureters, upon which they become pressed. The uterus develops much more to the right than to the left; it also inclines to the right, and besides this it undergoes a rotation on its vertical axis and turns in the direction of its greatest development—that is to say to the right, thus freeing the organs on the left side and exerting a greater compression on those of the right. Be this as it may, the facts that the ureteral obstruction begins at the level of the pelvic brim, that it is in some way due to the pregnant uterus, and that the right ureter is as a rule more obstructed than is the left have been repeatedly demonstrated.

Seeing that partial stenosis of the ureter by the pregnant uterus is generally regarded as the essential predisposing factor to this kind of pyelonephritis, it might very well be suggested upon theoretical grounds that the illness ought to be much more common and much more serious in those who have deformed and particularly contracted pelves and in those who have pelvic tumours, such as uterine fibromyomata or ovarian cysts, in addition to their pregnancy. These complications have existed in a few of the cases and theoretically they should play an important part in the pathology of the condition. Nevertheless, the existence of pelvic tumours or the like with pregnancy is by no means essential, or even common, as a cause of the pyelonephritis. The cases recorded have almost all had normal pelves and normal pelvic organs. The disease is therefore one which may arise in otherwise healthy women.

In regard to the question of whether a woman is liable to it during her first or a later pregnancy, opinions differ. It seems quite clear that the first few pregnancies may be quite uncomplicated and yet that pyelonephritis may develop during a later one; several observers lay stress upon its occurrence in primiparæ, but the truth seems to be that it may arise during any pregnancy and that in the differential diagnosis no stress can be laid upon the fact of the patient being a primipara or otherwise. It is clear that if obstruction to a ureter is an essential factor in the disease, the trouble is not to be expected in the earliest months of pregnancy. This is borne out by the cases themselves. The pyelonephritis may not appear until quite late in the pregnancy, but in the typical cases the mischief begins about the fifth month, as in the two cases described above.

The bacteriology of the pyelonephritis.—The bacteriology of the condition is very constant. In all but a very few of the recorded cases the organism that appears in cultivations from the purulent urine has been the bacillus coli communis. It has nearly always been in pure culture. Mr. Bellingham Smith found it in seven consecutive cases, and in only one case, recorded by Vinay, was the mischief attributable to another micro-organism—namely, a streptococcus.

There is some difficulty in determining the route of infection; this applies, of course, not only to the pyelonephritis of pregnancy but also to the similar suppurative lesions that may ensue when there has been residual urine in the bladder for a long time, even though no catheter or other similar instrument has ever been passed. The three paths by which the micro-organisms might, it may be supposed, reach the kidney are: first, from the bladder, ascending by the ureters; secondly, by the lymphatic vessels; or thirdly, by the blood stream. It must to some extent remain a matter of opinion as to which of these three paths is the more usual in these cases. Personally I agree with Mr. Bellingham Smith in thinking the blood stream the more likely route of infection, his arguments being as follows. Whereas it is true that, as Opitz urges, the female urethra always contains organisms and that the bladder in pregnancy is very liable to cystitis, nevertheless there are two objections to the view that the path of infection in the pyelonephritis of pregnancy is *viâ* the bladder—one anatomical, the other clinical. The anatomical objection is that the ureter in these cases is dilated, not in its whole extent, but only above the brim of the pelvis; the valve-like opening of the ureter into the bladder, which normally protects the former from infection, is still present and in perfect working order; there is no dilatation of the vesical end of the ureter, such as to cause a free communication between the latter and the bladder, and consequently there is no free path for the ascent of organisms from the bladder into the ureter. The clinical objection is still greater. The chief feature of pyelonephritis in pregnancy is the presence of pus in the urine without any symptom pointing to cystitis. None of the cases under discussion have afforded any evidence of preceding cystitis and cystoscopic examination in the severer of the two cases of which notes have been given showed that the bladder was perfectly healthy. There are no doubt other cases of pyelonephritis secondary to existing cystitis, the symptoms being aggravated by the existence of pregnancy, and in such cases the path of infection would doubtless be from the bladder just as it might be in a non-pregnant person; but in the cases of pyelonephritis under discussion there is no cystitis, pregnancy is an essential factor in the disease, and it seems unlikely that the organisms reach the kidney by ascent from the bladder.

Infection by the lymphatic vessels is very difficult either to prove or to disprove and there is little or nothing that can be stated definitely about it. Infection by the blood stream, on the other hand, is possible, and, if the vesical and lymphatic routes can be excluded, even probable. Experiments have been made on animals in which after artificial stenosis of a ureter purulent nephritis followed injection of bacillus coli communis cultures into the blood stream. Moreover, it has been shown that the healthy kidney sometimes excretes micro-organisms such as tubercle bacilli and typhoid bacilli in patients and animals who are suffering from an apparently local tuberculosis or from apparently uncomplicated typhoid fever. In these cases the micro-organisms have presumably reached the kidney in the blood stream, and if tubercle and typhoid bacilli can do so it would not be surprising if the bacillus coli communis did so too. The healthy kidney would eliminate the bacillus without itself suffering. The existence of stenosis of the ureter might well cause the urine containing such bacilli to stagnate long enough to allow of infection of the walls of the passages, even without supposing that there was diminished resisting power in the parts owing to the obstructed outflow. The ease with which the bacillus coli communis can reach the blood stream is well known from post-mortem examinations, where cultivations from organs situated far from the bowel nearly always yield this micro-organism in cultures made soon after death. It is held by some that a similar escape of the bacillus coli communis from the bowel into the blood stream can occur during life, particularly when there are abnormalities in the functions of the alimentary canal.

This raises the question of whether the pyelonephritis of pregnancy can occur when there has been no abnormality in the intestinal functions, or whether, in addition to pregnancy and partial stenosis of the ureter, some error of the bowels, particularly constipation, is essential to its production. This is a very difficult matter to decide. It is very certain that a great many pregnant women may suffer from constipation without any other deleterious effects. Nevertheless, granted that a patient were on the verge of developing pyelonephritis, the existence of severe constipation might very possibly cause a certain number of colon bacilli to enter the blood stream and thus prove to be the final or determining factor in the illness. This seems to have been the case, for example, in connexion with the second patient described above; always very costive, she was suffering so much from constipation just before the pyelonephritis set in that she could only get her bowels to act by the use of repeated enemata.

The effect of the pyelonephritis upon the pregnancy.—A number of questions arise, to each of which the physician may be required to give an answer if he can. Amongst these are the following: To what extent does the pyelonephritis interfere with the course of the pregnancy? Is it likely that the child will be born dead? Seeing that pregnancy is a fundamental factor in the pyelonephritis, ought obstetrical measures for the termination of the pregnancy to be advised? Is the time of labour one of special danger? Is the patient particularly liable to uræmic symptoms? Is there any relationship between pyelonephritis and puerperal eclampsia? Is the condition likely to be completely cured after labour, or is a residuum of kidney inflammation to be expected? Is the patient very liable to have a recurrence of the pyelonephritis in a succeeding pregnancy?

It is only by a collective inquiry, in which mild as well as severe cases are included, that conclusive answers can be given to these questions. Under present conditions it is dangerous to base opinions upon published cases only, because those which are thought worthy of being published are often not the ordinary cases but rather those which present points of special interest. On the other hand, an individual can scarcely hope to meet with a very large number of cases himself, so that until records of consecutive and unselected cases can by some means be gathered together it is only possible to base one's opinion either upon recorded, and therefore selected, cases or else upon the few cases that one has oneself watched.

It would seem that, diagnosed early and treated by confinement to bed with antipyuric remedies, the condition usually tends towards resolution, notwithstanding continuance of the pregnancy. Moreover, in the majority of what may be called cases of ordinary severity the pregnancy is not particularly apt to come to an end prematurely. The children do not show any special liability to die in utero and the mother is not subject to uræmic convulsions at the time of labour. No doubt there are individual cases in which the illness is so severe that it might be wise to advise relief to the ureteral obstruction by the use of obstetric measures for emptying the uterus. The kind of case in which this might be the best course to follow would probably be one in which the renal mischief had set in with severity during the earlier months of the pregnancy and had then persisted for a month or more without abatement in the symptoms, notwithstanding all the medicinal treatment available. Such cases as these are distinctly the exception, however. The majority of the patients require the adoption of no obstetrical measures for the time being. Treatment upon purely medical lines, by absolute rest in bed, light nourishing diet, laxatives, and such drugs as are known to benefit pyuria, begun early and carefully followed, will usually relieve the patient of her untoward symptoms comparatively soon—that is to say, within three weeks or a month. The pyuria will often persist for a month or six weeks after the patient herself feels quite well, and unless considerable care is observed a relapse is apt to occur before the pregnancy reaches term. Repeated microscopical examination of the urine is therefore essential, and medical supervision is required as long as any pus is present. Eclampsia is not to be expected and the patients nearly always get perfectly well of their pyuria after the child has been born.

It would not be at all surprising if similar pyelonephritis were to recur in succeeding pregnancies, and cases are on record where this has actually been the case. This is not the invariable rule, however. If the pyuria is completely cured after one pregnancy, and care is subsequently taken to insure that there is neither constipation nor diarrhœa such as might predispose to invasion of the body by the bacillus coli communis from the intestines, it is quite possible for a succeeding pregnancy to pass by without any symptom of pyelonephritis at all.

In conclusion of this lecture, stress may well be laid upon the fact that the pyelonephritis of pregnancy may easily be mistaken for something else. The milder cases may be regarded as simple pain in the back, as lumbago, as influenza, and so forth; severer cases may be thought to have pneumonia, pleurisy, or the like; the most severe cases may be diagnosed as appendicitis or as some other intra-abdominal condition. The main symptoms of the disease are backache and pyrexia, with or without headache, vomiting, or rigors, and unless the urine is carefully examined for pus corpuscles the real cause of the trouble might readily be overlooked.

A Lecture

ON

THE SPECIAL PSYCHOLOGY OF WOMEN.

Delivered at the Institute of Hygiene on March 10th, 1908,

BY THOMAS CLAYE SHAW, M.D. LOND., F.R.C.P. LOND.,

LECTURER ON PSYCHOLOGICAL MEDICINE AT ST. BARTHOLOMEW'S HOSPITAL, LONDON.

LADIES AND GENTLEMEN,—By psychology we mean the mental processes in their subjective and objective ramifications, what they appear to be, or should be, to the individual, and what they are, or should be, to the external world—to society in all its gradations. To speak on this subject presupposes that one has, at least to some extent, such a share in the form of mental action as will justify the audacity of criticising what can only partially be experienced. This would be easy enough in the uni-sexual mind, but women are women and men are men, and though there are points of resemblance, both in bodily and mental structure and function, there are yet such profound differences that the one must always be a puzzle to the other. We may be able to say what women ought to do, but that we find them acting and talking very differently merely proves that we have not correctly estimated the factors upon which their motives have been formed, and since a complete fusion of intellects is not possible the psychology of women must always remain a paradox to men. It is a different form of mind that we are asked to appreciate, and it is no more possible for the mere man to predict what the mere woman will of necessity do than it is for the timid person to understand the *audace* of a lion-tamer or for the rat-catcher to flee at the presence of a mouse. And yet this dis-association of mind in the two sexes is not a complete one; there are many common features. There are men of whom it may be said that there is much of the woman in them and there are what are called masculine women who seem to be composed largely of the attributes of the male mind. We shall see that much depends upon education and environment and that except in one particular direction there is in reality little difference between the two classes of mind—that one may be complementary to, or may largely replace, the other, and that it is quite feasible to suppose a society in which, *quâ* mentality, the position of the sexes was reversed; indeed, such a state of things did exist in the old Basque provinces, where the judges were women and women exercised the suffrage!

Up to a certain point there is little, if any, mental difference between the boy and the girl. Except for dress it would be difficult to tell one from the other, and perhaps also of environment, and in these days the conditions of the latter are so similar in the sexes that until the parting of the ways (the changes at puberty) there is no distinctive mental difference between the sexes—the one might sit as understudy to the other, either in work or play, and no one would be the wiser. Granted that differences in dress at an early period and separation in domestic arrangements do tend to make the child recognise that *he* and *she* are in some way different, this is entirely an artificially grafted idea and in no way affects the position that at first and for a long time afterwards the mind of the one is the mind of the other. The boy and girl are each others' playmates until at puberty a marked change in their relations to each other occurs—he who was up to then the trusted *alter ego*, treated with confidence and in a spirit of equality, is now viewed as an objective of a very different character, he is a person to be kept at a distance, to be treated with reserve and regarded with suspicion, and this change of relationship is more or less fostered and maintained for ever afterwards: life from being asexual becomes bisexual.

What grounds are there for saying that woman is inferior to man? What is the local sign of inferiority? Hitherto it has been shown chiefly by submission to authority, a smaller range of idealism, a more delicate and therefore less strong bodily organisation. There are other signs, but I will [illegible] the three named as representative of the general rela[illegible] of the sexes in the past, just to point out that under [illegible] conditions of education and environment these [illegible] of "inferiority" have almost disappeared. The [illegible] is that women are not inferior to men; they are different from them, scarcely perhaps comparable, *in some faculties* superior; and to talk of "inferiority" is like comparing two masses of different composition and calling one inferior because it is not so large and gross.

In old times brute strength or force was the sign of superiority, so the woman was in this particular inferior; she had to stay at home chiefly because of family duties, more especially with relation to the children. Naturally, too, she was kept out of the State deliberations and her intellect had no chance of developing. Therefore she had to protect herself and this she could do only by intellectual or mental means; hence she would seek out the weak points of the man in order to enlist him on her own behalf, to which end she would employ ornaments, scents, flattery, particular enticements, &c., all calculated to appease his wrath and to retain his protection. The childless woman would come to be viewed as useless to the tribe and as a dangerous person, because she was of no use to the commonwealth, and, moreover, having more leisure, she would perhaps become revolutionary, hence she would be suppressed, and so the laws enforcing the subordination of women became very strict. How it ever came about that women were elected rulers of tribes was probably due to the fact that by accident there was no male survivor and that any opposing male faction was overcome by the adherents of the old house who were probably bribed to support it. As long as the interests of women were not antagonistic to those of the men this "inferiority" continued and would most likely have still continued had it not been for dissensions among the men themselves. Influenced by this or that a section more favourable to women would be formed and by constantly driving in the wedge women succeeded in establishing a place for themselves. When men ceased to hold women on a curb these soon got to resent even the snaffle, until at last they bid fair to go on their own untrammelled way and there is now rampant the positive enmity of strife, the position of the tyrant man being gradually forced and much of his so-called privilege curtailed, shared, or even abolished. The delay in taking a fortress does not necessarily show "inferiority," it may only mean that time is required or that all the assailant strength has not been put forth. Argument from the animal kingdom is perhaps scarcely to the point for our purpose because of the development of the upper and higher brain centres in human beings, but in some respects human beings and animals are alike, for in both the different sexual conditions bring about the same class of results; the mal animals fight for the females, so do men. The femal animal shows courage and devotion for its offspring, so does the woman; the animal cares nothing for its father (probably never sees him) and nothing for its mother after the period of suckling is over, and so it would be with a man were it not for the development of the intellectual centres; the animal in distress never thinks of its parents, the child in distress still expects his parents to protect him, and the young man who wants money knows that the mother does not live who, having in early days nourished him, would ever refuse her last coin or jewel to help him.

Women, being of less powerful muscularity than men, have to protect both themselves and their children by artifice. Woman is a prize, but as there are many candidates for the prizes she has to resort to artifice to obtain the victory of marriage. She has to fight just like the man has, but she does it in her own way. Hence she is deceitful, both in dress and presentation; at times she hides her charms, at others she exposes them. She resorts to false hair, to false teeth, to face powders and lotions, to beauty preservatives, and to ornaments. These are decoys and must be considered fair game. There is always an excuse for these periods of rejuvenation; they connote conditions of health. If artificial teeth conceal imperfections they also aid digestion; if "transformations" cover up baldness they also prevent cold; if face powders hide blotches and wrinkles they also prevent irritation of the skin; whilst face massage promotes a return to plumpness and resiliency. As to ornaments, the use of them, except as signs of the possession of wealth, or as the parade of ancestral relics, or as significant of official dignity, is not so clear; certainly they are very useful for purposes of trade. It is said that diamonds are irresistible to the female mind. May this always remain so. Think of the awful cataclysm that would ensue if women changed their views with regard to diamonds! But for this female passion the Boer War need never have been fought, and without its diamonds South Africa is practically useless. The "superfluities" of life are as important as the "necessities"; in fact, the commercial value of "expensive tastes" is a large asset and without these many working industries would be crippled. Just the same holds with regard to dress. The frame of the body is practically made of three triangles and there is a definite mode of covering adapted to each. At first (as is even now the case in some places) there was no clothing at all, but owing to two conditions—viz., climate and imperfections—dress or covering became a necessity, and then as affording opportunity for the display of wealth and superiority it developed into luxury. Where, as in the case of *religieuses*, it became necessary to subordinate the altruistic to the selfish and to the purely ideal dress was employed to conceal entirely the figure and form, even the face was hidden, and the veil of to-day is probably the trace of this. Dress, either as a protection against the weather or as an opportunity for hiding or displaying the curves of the figure, is so important a factor in the life of a woman that the prominence she gives to it is easily understood; it is a necessity that she shall show herself off to the greatest advantage and not pure vanity. Women have various objectives in dressing as they do, perhaps they inherit tendencies in this way and would be at a loss themselves to account for their feelings and ideas in this direction. There is truly a psychology in clothes and it is useless to say that women dress to please men or to excite the jealousy of other women, they just dress in their own way because they have to and for their own satisfaction, and though precept and environment may count for something there *is yet* the idiosyncrasy of the woman behind it all. She may have any number of new and fashionably cut clothes but she appears in a garb which her friends cannot understand. Why? Because of a mental trend which cannot be reduced to rules and society codes. The psychology of dress is that it makes you think that you are what you profess to be. That is why the common soldier is never allowed to appear except in uniform and why the priest always wears his black clothes and white tie. The mind of the insane is on the same psychological basis as the sane persons. I have known female lunatics who had delusions of "position" don on special occasions ("collar days") such jewels and ornaments as they could lay hands on, glass set in string or wire for rings, scarlet Turkey-twill sashes, Orders of the *Garter*, conspicuously displayed, in all respects like the orthodox social models.

The consideration of the psychology of women is perhaps best based on an analysis of what are called the elements of mind—here we shall see that in some respects they are in a plus, or positive, state, in others in a minus, or negative, condition. A good deal has been made of the assertion that the brain of the man is heavier than that of the woman, but Marshall showed that by comparing brain weight with the stature in the two sexes the weight (of brain) for each inch was 0·708 in the male and 0·688 in the female, this difference being entirely due to the preponderance of cerebrum in the male, and that if the other parts of the brain are taken it was identical in the two sexes. He showed that tall persons have relatively less brain substance than short ones and that if the height in inches is divided by 1·6 the weight of the brain in ounces is obtained. Then, again, we know nothing positive about the relative qualities of the brain in the two sexes and no one can tell under the microscope whether he has a male or female brain to deal with.

The mental faculties (to use a term which is not altogether defensible) may for practical purposes be divided into—

Sensation; perception; memory; feeling, emotion and sentiment; and ideation and conation { attention,
impulse,
will power.

We cannot prove either from anatomy or physiology that any one of these "faculties" is, or should be, greater or less in women than in men. We can only judge by experience and analysis that whilst in some of these divisions women are practically of the same intensity and quality as men, in others they are either excessive or defective, but pray bear in mind that this is only empirical or experiential knowledge, and that the estimation varies according to the personal equation of the investigator. As to sensation, the quantity and quality seem to be about equal in the sexes, except that the sense of smell is perhaps more acute in women, probably because in men the nasal mucous membrane is blunted by snuff and tobacco. One always notices more open windows in carriages occupied by women. Perception (or the knowledge of what is implied by sensation) is probably the same in the two sexes. Memory—equal, whether as purely abstract memory or as the result of association. I believe that on the stage women are more word-perfect in their "parts" than men are, but there are reasons for this apart from the question of pure memory. In imagery or ideation the range may be as great in one sex as in the other. How often does it happen that in the highest flights of poetry, in questions of abstract mathematics, in the application of scientific theory, in romance, in practical government, we find the woman just as prominent as the man. In the departments of feeling and emotion and in the conative section it does, however, appear that women differ materially from men. To feeling and emotion they are especially susceptible and they seem to be more liable to act upon impulse which in itself proves want of inhibition. The real origin of feeling (sensation) and emotion (ideal or intellectual) is doubtful. There are different theories on the subject of it. According to one we are sad because we cry; according to another we cry because we are sad. The former make the feeling or emotion secondary to the muscular and organic (heart, lungs, &c.) display, whilst the latter make the emotion the primary condition, the display of the emotion being actually secondary to the sensation or feeling. Certainly, whether on the stage or in real life emotion and its display are far more conspicuous among women than men, and it would seem that there are special reasons for this.

The latest conclusions point to the basal ganglia as being the most intimately concerned with emotional display and these appear to be relatively larger in the female sex. If pain and pleasure be taken as the equivalent for sensation, we may say that joy and sorrow correspond with these in the realm of emotion. Moods are more permanent states of mind than emotions proper, and violent emotions are termed "passions." Now these emotions have an objective and a subjective side, and those who are strong on the one side usually show strength on the other; and joy, like sorrow, assumes different forms according to the direction which it takes—though, by the way, we have not nearly so many words to express joyous emotion as we have to express sorrow. Thus like and dislike are the most general forms of objective emotion corresponding to joy and sorrow on the subjective side. Sorrow directed upon the object which excites it is called "care"—we can only be full of care about others; when subjective it is "melancholy." One theory is that pain and pleasure, joy and grief, represent just what is harmful to us and what is of advantage, that therefore we recognise that when enduring grief or sorrow we are in a mental condition analogous to pain on the bodily side. If so, pain and grief may be conservative to both body and mind; as long as they are there we know that something is wrong and we must strive to remedy it, just as insomnia calls our attention that there is something lacking in the periodic return of rest, and that therefore it is a sentinel to warn us that we must be on the alert to find out where the mischief, of which the insomnia is the sign, lies. Now what is the object of emotion? Why is it so important in our mental category? There are people who pride themselves upon never having feeling or emotion; they say that nothing moves them, they are impassive, never excited, never depressed, everything that occurs is to them a matter of course, and from their altitude of serene indifference they behold with a sort of neutral contempt their more demonstrative congeners. Premising that they are correctly describing their subjective states the condition is not one to be envied, for it is the mental attitude of the degenerate and the imbecile, who scarcely know what feeling and emotion mean except in the very lowest degree. The expression of emotion is both conservative or protective (when it is essentially reflex) and deliberate. The first glimmer of intelligence in the infant is the smile responsive to that of its mother. Is it not well that the dawn of intellect shall be heralded by happy auguries? And in the bodily and facial expressions of fear or of anger the woman appeals in the only manner possible to the protection or sympathy or other mental states of the man.

Two very prominent emotions among women are obstinacy and sympathy. It is obstinacy which comes to her aid when she is beaten and it often makes her illogical, not that the woman does not see that she is wrong but that being used to conservancy she wishes to preserve intact the stand she has taken and therefore she argues that by persistence she can wear down the attack, and as she knows from former experience that defence is useless without attack she is not only obstinate but recriminative. The wise man knows—or ought to know—that a woman's obstinacy is merely the evidence of the strength of his attack and probably of the successful issue of it, and noting this he should not blame the woman, for it is often her only rampart. It is at times best to concede gracefully the point at issue and to let her march out with the honours of war. In sympathy we note a device for setting up in others a frame of mind similar to one's own, so that what is wished for may be gained, or else a desire to enter into the feelings or mental attitude of another person so as to ascertain, if possible, the object of these others in pursuing a certain course of action, or else by showing sympathy to make it evident that they agree with the opposite party, an agreement which will be to the benefit of the sympathiser certainly in that the feeling of support is stronger towards those who think in the same way—and the forms which sympathy takes vary according to the motive of the woman. It is now of the gentle, soft, and low-voiced form (so excellent a thing in woman, as King Lear said); at another time it takes the martial, active, strident type necessary to harmonise with and complete the unity of mind the *vis viva* of which it is sought to obtain. The suffragette question is perhaps the best example of the extent to which these two emotions of obstinacy and sympathy will carry women. Their wonderful obstinacy is due partly to a sense that there is really no good reason why they should not have a vote if they wish it, partly to the idea that they can by this same obstinacy break down the opposing strength (for it is really a fight for freedom from the restraints of the majority), and by their powers of objective sympathy they endeavour to arouse corresponding emotions in their antagonists. They see that a few men are (or say they are) in their favour and so they appeal to these traitors in the camp in the hope of spreading disaffection, for they know that they can only get what they want by the consent of men, and as the authorities seem determined not to let them have it, there but remains to view the present position of the suffragist as a necessary consequence of her mental equipment. We notice that pain and worry on the subjective side beget sympathy towards others. Women are more sympathetic than men because physiologically they have to endure more—the community of bodily pain and mental worry is plus or positive on the woman's side, and in this way they have more sympathy. Sympathy is never true without experience; it is the endeavour to give external support by making others believe in the reality of what they are saying or doing—it is, indeed, a form of flattery. Another plus-emotion in women is jealousy. *Women having appropriated* the male element do not mind how the latter deals with them as long as he does actually confine his attentions to them. Jealousy implies the rankling sense of inferiority, that something is *lacking in their attractiveness* or in their duty. It is jealousy which prompts to violence and to murder more perhaps than anything else (except drink), and arising as it does from one of the earlier and lowest developed parts of the brain it *partakes more of the nature of an instinct*—i.e., that of self-preservation—and therefore it should always be gently estimated. The only way to overcome the feeling is by education and the use of the higher brain, but in the capacity to do this is just where the lower grades of society fail, hence crimes due to jealousy are more frequent in them.

A great deal is said about women's desire for amusement, as if it was a special *proprium* of the sex. Is this so? I do not find that where women have plenty to do they require an inordinate amount of it. Given strength of body they naturally must expend their neuro-potential, their energy, in some way, and of course they naturally take the easiest way. So do men when they have no work to do. It is said that nowadays women do not care to have large families because they want to enjoy themselves, but it is probably the other way about: it is the want of families that drives them to seek amusement, and yet though we ought to admire the efforts they make to employ themselves there is an advantage to others when women choose to enjoy themselves, for they irradiate brightness to others. Often the so-called "enjoyment" is merely hard work to avoid *ennui*, and the women who grizzle because of the distaste for, and decay of, home life in their daughters, which makes them always on the rush for going away, for visiting, or playing hockey or tennis all day, should remember that it is chiefly because the home life is conducted in a dull, monotonous, cramping, and enervating spirit. Still, there must be some butterflies, and the woman beautiful, the well-dressed, the decorated and adorned, she who apparently has nothing to do but to be gracious, must not be deemed vain and useless—she is fulfilling a part in the order of nature as surely as her more humble sister in the sombre hues of workaday necessity. That these bright creatures work hard in their own way ought to be appreciated, see what privations, what training, what fatigue, have to be endured to maintain the rôle. Health is a very good thing, but it requires hard work to maintain, as well as restraint. There is one phase of emotional expression which has strong bearing on one of the most distinct of all the emotions, love. I refer to this that especially among the upper classes expression of emotion is either a thing of the past (it being thought "bad form" to show what is thought or felt) or else it is purposive or is relegated to the province of the actor. There is, however, no doubt that the emotion may exist without any external sign, and perhaps women suffer from this repression. What a relief expression gives to an emotion. How painful almost to bursting-point is the effort to suppress it. Men confess to difficulty in understanding the action taken at times by women in the presence of this particular emotion. They may show the greatest nonchalance when they are feeling the most strongly, and without doubt by enduring they may imperil their chances of success. Well, they prefer to take the risk. The clue to this seems to be partly due to the instinct of self-preservation, waiting to see how real the feeling of the opposite party may be, partly to the idea that the ardour of the attack is generally in *direct proportion to* the resistance, and partly to self-conceit or pride. There may also be the idea of the unreality that often attends emotional display.

In considering woman's rôle in the conative faculties—voluntary power and impulse—I will say that we know of only one reason why they should differ in quantity and quality from what they are in the male, and that is the possible excess in development of the very highest centres in man, which on evolutional lines are the last developed and the most inhibitory. But as a matter of observation we (men) have come to the conclusion, rightly or wrongly, that they are more impulsive and less inhibitory than men are. Perhaps this is true, but if so I think that it is a condition due mainly to circumstances and to education and that the balance will or may be as fully established in the one sex as in the other. Impulsive conduct is the most simple form of voluntary action; it occurs in the young whose higher inhibitory centres are not yet developed, in the degenerate where they never can be developed, and to some extent in people who have to protect themselves and their children, and it is indeed very like the action of instinct though not altogether like it. True, voluntary action means the balance of motives; it is a higher and later development than is impulsive action; it is a higher educational phase and is, therefore, in accordance with the laws of development, the first to go when decay sets in. If it is true that women are invariably more impulsive than men it would point to this, that in general the female mind is not of so evolved a type as the male, but the potentialities for complete inhibition exist in the one just as much as in the other, and any "inferiority" in this particular, if, indeed, it exists at all, is accidental and may in time with education be compensated. Feeling or emotion enters very largely into the composition of voluntary and impulsive action and therefore we have good reason for concluding that women in whom the emotional factor is strongly developed must show strong impulsive and voluntary action.

Our analysis has then led us to the conclusion that woman has some advantages and some hindrances. She is very *quick in perception and unfortunately (at times) is quicker* in action: thus excessive impulse helps her in protecting herself and her children; it, however, at times lands her in awkward circumstances.

It is often asked, "What have women done in advancing science?" Well, they have only just begun to study it. In idealism in writing they have equalled if not excelled men. It is often difficult, where no names are given, to say whether the book is by a male or a female author. When I was examiner in psychology at the University I could not tell the sex of any of the writers of papers either from the handwriting or from the matter, and it often turned out that on getting the name corresponding to the number of the candidate I was mistaken. In the rôles of life women have prejudice and long oppression to combat but except from the way in which they are handicapped sexually there seems no reason why they should not do men's work just as men may do women's work; in fact, the terms "men's and women's work" should cease. Generally speaking, what one can do the other can also.

Cruelty in women.—If the *proprium* of the woman is to have and to bring up children she must be on the look-out for anything likely to hurt them; hence her indifference to the welfare of others as long as they stand in her children's way, and this makes her possibly cruel; moreover, if she is disappointed in the way her own children turn out she may turn against them and be cruel to them. For this reason married women are very *patriotic*, for patriotism is based upon the desire to protect our own from the intrusions of the alien. Self-interest due to inherent weakness must engender craft, obstinacy, cruelty, recklessness of means to secure an end, personal adornment (to attract), quick perception, action on impulse and, if necessary, artfulness and the capacity for waiting until success is assured. If for a moment one turns to the mode in which insanity shows itself among women as compared with men, one finds that[1] it is characterised by excess in women, of impulsive acts, of tendency to suicide, of destructiveness.

What is the psychological future of women? They outnumber men, they are taking on the occupations of men, they cannot all be married, and as much of one (the chief?) side of their nature cannot be developed their complete psychology must be impeded. Polygamy cannot be thought of: it entails too much hardship and loss of freedom. Free love is out of the question. They will become abortive both in body and mind and will be a different thing from what we now know. They will develop certain aptitudes which they may happen to possess and therefore will become notable in certain ways of intellect and work because their environment will become extended. I see no limit to their occupations, and if by dint of obstinacy they do get into Parliament they will first participate in and then monopolise; they will by sheer weight of numbers bring about such social conditions that a revolution will ensue—the men will turn and rend them. The married woman instead of being looked upon as the honoured and favoured one will be voted by single sisters as an impediment to her plans for subverting the position of the sexes, and I think that the married women see this and therefore they take side against the propaganda of the suffragette, against education, against professional women, because they see that it leads to the loss of the sex-mind and tends towards their socialism—it is just a form of slighting or disappointment. The repression of the sexual element of mind in the woman leads to a nondescript creature whose instincts are abortive and whose life eventuates in selfishness.

---

[1] See article, The Sexes in Lunacy, St. Bartholomew's Hospital Reports, vol. xxiv.

So then some of the elements of mind are more or are less developed in women, but there is no special feminine element, no factor present in one sex which is without counterpart in the other. The sole difference is the separation of the sexes and of some attributes specialised through this.

The fusion of the two sexes in one individual does not exist in the animal world: it would be too risky, it would lead to effects disastrous for the young. In the same way the fusion of the two qualities of mind in one individual would lead to a negative conduct. It is only poets and novelists who have made women mysterious by intensifying (caricaturing) the action of the mind-elements. It may be difficult to guess all the motives which result in a certain course of action, but when once explained (as they often are only *after* the event) the results are seen to be the things which only could have happened. The form of brain action is identical both in men and women, sane and insane. The household—the family life—represents the unity of life, and the happy and well-ordered family represents the harmonised incorporation of the two minds and bodies. But these small commonwealths are moulded on an equation formed by two elements selected and adjusted to each other, and they will not brook anything except modified interference and that by force and law. It is probable that mono-sexual judicial authorities are alone tolerable because the presence of the other would arouse the affinity-element and this would lead to a unity of conclusion not always in the best interests of the majority. As to occupations it does not matter whether the two sexes are represented or not, because the employing of either is quite a voluntary matter, but for imperial purposes mono-sexual predominance seems requisite. This mono-side may, of course, be the female. Hitherto the men have been the stronger and have held the position; let the women take it if they can.

I have tried to prove that it is the sexual element which has handicapped the woman, which is accountable for any peculiarities of a distinguishing and repressive nature; that were it not for this there is practically no difference between the potentiality of the two sexes. But what a world it would be if there was only one mind in a bisexual race? It would be a short-lived and uninteresting world. There would be no object in striving, no economy, no altruism, no ambition, no patriotism. See, then, the influence and the importance of the continuation of the species!—how it becomes a duty: without this element we have nothing but idealism, braininess without emotion, a class of mind we cannot conceive any more than we can imagine what the future "heaven" must be where they "neither marry nor are given in marriage," a sexless, spiritual existence.

As the sexes have developed in different ways, so have the accompanying mental and bodily divergencies become emphasised; from not fighting the woman has become more timid and less assertive, but she has developed invective and persuasion, and now that she has strength of numbers she is developing force. The man is perhaps more compliant, he has up to now shown the chivalry of strength, he was always willing to avail himself of women's help, and in these later days he shows it by marrying for money. Why are women so up in arms against *being married* for their money? One generally finds that the men who marry women with money are of all husbands the most docile owing to the sense of dependence. Perhaps the fact that women have not always had money has tended to make them dependent, afraid to contradict, more obedient, less assertive; but now that the position is so often reversed we see that the real mind in the sexes is the same altered only by social necessity and environment.

People run away with the idea that mind in either sex is something very complicated, very profound, and very different in kind according as we see its *manifestations* in the man or the woman. This is a mistake. As a rule, thinking is a very simple thing, scarcely more than a reflex. Wundt's dictum is that the old metaphysical prejudice that "man always thinks" has not yet entirely disappeared. "I am inclined," he says, "to hold that people really think very little and very seldom." Many an action that looks like a manifestation of intelligence most surely originates in association. People talk about "work" as if it were the *proprium* of one sex not to be aspired to by the other, whereas there is no work peculiar to the one or the other. Everyday work is just a matter of little brain necessity; it may be a "bother," a "bore," but it involves little beyond reflex mentality. One sex might carry on the work of the world just as well as the other. Left to itself without work or occupation mind degenerates into subservience to the body; the man or the woman with nothing to do spends the time selfishly, cultivating the appetites, tending to introspection. Insomuch as there is any difference between the minds of the woman and the man it becomes an interesting puzzle to the one to guess what is going on in the other. When from force of training and similarity of environment it is seen that the minds are essentially similar then interest disappears and life becomes monotonous.

It is for women to say which they choose, whether they will still prefer to retain the position which long education and environment have given them, with the result that there is a difference which makes them the sought and desired companion of the man, or whether they will prefer the form of training and environment which, whilst it shows them capable of equalling the mental aptitudes of the man, reduces them to the mere question of being a physiological necessity. That the *weibliche* should remain the *ewig-weibliche* is, I think, the hope of the man and it would seem to be the happiest thing for the woman to lay this in its essentials to heart and to be satisfied with her position of a freely-accorded honour and devotion. Men expect in women something complementary to themselves, something to fill up their own sense of incompleteness, and they experience a feeling of disappointment when they see that women try to prove that after all there is no gap. Men want a *locus penitentiæ*, another phase of mind which shall enable them to idealise and to realise these ideals, because they feel that after all analysis, after all attempts to prove that the one sex is practically the other, there is something which they miss when left to themselves. There is something inscrutable in what seems to be the natural instinct of the man to assume that the woman is really the weaker vessel, that therefore she must be treated with consideration, with reverence, as a thing to be cherished, that there is a mystery about her which he cannot penetrate, and it comes to him as a shock to find that in these modern days she insists on considering herself to be the same thing as himself. He has hitherto viewed her not merely as a companion or a nurse or a plaything but as something different which he might worship and cherish without thought of rivalry, which he might yield to with grace with no loss of dignity on either side. Is it worth while to destroy his illusion? Is he now to find himself mistaken? Surely women will hesitate before they exchange the invincible armour of mystery and charm for the naked and tame theory of equality and similitude!

OPHTHALMIA NEONATORUM: AN EXPERIMENT IN TREATMENT.

BY A. NIMMO WALKER, B.A., M.B., B.C. CANTAB.,
M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT SURGEON TO ST. PAUL'S EYE AND EAR HOSPITAL AND TO THE SCHOOL FOR THE INDIGENT BLIND, LIVERPOOL.

With a Note by A. A. MUSSEN, *B.A., M.D., B.Ch. Dub., D.P.H. Cantab., Assistant Medical Officer of Health and Inspector of Midwives to the City of Liverpool.*

THE unsatisfactory nature of the treatment of infants suffering from ophthalmia neonatorum must have impressed itself upon everyone who has had experience of such cases in the out-patient departments of our hospitals.

As a rule, the child is not seen until the disease is firmly established, with lids swollen and conjunctiva infiltrated: it is brought day after day, week after week, even month after month, until recovery occurs, or with threatened sloughing of the cornea it is admitted into hospital, often too late to prevent permanent damage or loss. Nevertheless, I had not realised for what length of time some cases have to attend, for babies are very like each other, except, of course, in the eyes of their mothers, until a strange case was brought to hospital, in which the upper lids were everted completely by the violence of the inflammation. This eversion probably saved the eyes, as it gave free vent to the pus; but the sight was an ugly one and identified this particular baby in my mind. At first I was very interested in the case and showed it to the students who attend the practice of the hospital, but as week after week passed I gradually began to be rather ashamed of it and to wonder when it would be finished. In the end the child recovered but took two months in the process and the mother had to bring it daily for all that time. This led me to have a record kept of the length of attendances of such cases, and to my surprise I found that this was not altogether an exceptional time in severe cases. Yet all this long treatment and danger could be saved if only the disease could be attacked vigorously in its early stages. The following cases supply proof of this assertion.

Some years ago one of the honorary surgeons was summoned late at night to St. Paul's Hospital to see a patient who had just been admitted with severe purulent ophthalmia. He remembered rubbing his eyes on the way home, being sleepy. About 5 A.M. he woke up and found that his eyes were injected and discharging a thin muco-purulent secretion; fortunately, he had some zinc chloride at hand and made up a solution of 0·5 per cent. which he kept dropping into his eyes until the smarting became too severe. He fell asleep again and on awaking found that there was still a discharge, so he resumed the use of the drops. Having to go to the hospital in the afternoon he went out but on the doorstep the pain caused by the bright sun was so severe that he absolutely spun round. However, with the aid of dark glasses he did his work and by the next morning his eyes were well. The patient, a young man, lost an eye.

The other two cases occurred in nurses at St. Paul's Hospital. One was the nurse in charge of the ophthalmia cases. The attack began in the afternoon with congestion; by the evening there was a purulent discharge and the lids were beginning to swell. She was sent to bed and the eyes were washed out with zinc chloride lotion. On the following morning there was still a discharge and argyrol 25 per cent. was used which, in her words, "stopped it at once," and she was back on duty on the following day.

The other case was that of a nurse on night duty who felt her eyes sticky in the evening: by the morning the lids were swollen and there was a purulent discharge. She was treated on similar lines to the other nurse and was back on duty in [illegible] days. These nurses have learnt their lesson and now obey orders and wear rubber gloves when dressing such cases.

These cases satisfied me that the disease is very amenable to treatment if attacked vigorously at its onset. But this is the very treatment which the average case does not receive, owing to the impossibility of carrying out, in the homes of the poor, frequent and thorough irrigation, both by day and by night. An example of this difficulty is the following case, where a medical man and nurse did all that was possible but with unsuccessful result.

The child's eyes began to discharge on the second day. A medical man was called in on the fourth day and arranged that a district nurse should come two or three times daily; he himself came once a day. Nevertheless, when the baby was brought to St. Paul's Hospital six weeks later both corneæ were perforated.

The indication, then, is the admission of cases occurring among the poor as soon as possible after the beginning of the disease into an ophthalmic hospital where vigorous treatment can be carried out both by day and by night. Having arrived at this obvious solution of the problem I was met by the equally obvious difficulties of, first, the danger of infection from the introduction of such cases into hospital, and, secondly, the necessity of the admission of the mother to feed the infant. The first difficulty was solved by the turning of a small ward into a nursery by the addition of cots and the appointment of a special nurse who is not allowed to touch clean cases. The second difficulty was much more serious and threatened to wreck the scheme. In addition to the prejudice to be overcome the risk of moving a lying-in woman in the first week had to be faced. I realised that an ambulance was necessary and could only be provided by the city authorities, so in the absence of Dr. E. W. Hope, medical officer of health of the city of Liverpool, I applied to the assistant medical officer of health (Dr. Mussen). At once he welcomed the idea and promised that an ambulance should be sent whenever required. Moreover, he told me that under the Midwives Act the health committee is responsible for the control of the midwives and under the Notification of Births Act the medical officer of health receives notification of all births within 36 hours.

Here, then, was the machinery ready to hand. Births are notified to the health department and a lady inspector visits those of the poorest class which are attended only by midwives or handy women. If she finds a baby with discharging eyes she tells the nurse to obtain medical assistance, or if too poor to take it directly to hospital. There it is seen by one of the surgeons, and if necessary detained while the health authorities are asked to send an ambulance to bring the mother. Mother and child then are put in the special ward and attended by the special nurse. Equally this arrangement applies to cases sent by general practitioners who doubtless will be glad to be relieved from the responsibility of these tedious and unremunerative cases. Of course, it is within the right of the mother to refuse to come in, in which event the baby is sent back with instructions that it must be brought at least twice daily, but I anticipate that such refusals will diminish as the ward becomes better known.

I hope also that the ward will prove of educational value, both to students and to midwives, and that it will be possible to arrange that in the curriculum of midwives in Liverpool a demonstration may be included of these cases in the height of the disease, together with examples of the results of its neglect in the persons of inmates from the Blind School. This ward is the realisation of a scheme which I proposed in March, 1907,[1] and which I elaborated in a paper read at a meeting of the North of England Union of Institutions, Societies, and Agencies for the Blind, held in Liverpool in December last. At present it is only in its beginning, having been started on Jan. 1st of this year, but I hope by this preliminary note to arouse interest in, and to evoke criticism of, an experiment in hospital and municipal work which I believe to be quite new, at any rate in Great Britain.

Note by DR. MUSSEN.—Much has been done in recent years to prevent the lamentable results of ophthalmia neonatorum, but there is still a very large number of blind children who owe their blindness to this disease. It is with this object that Mr. Nimmo Walker has suggested the scheme which he sets out in the preceding paper, and which appears to be the only scientific and radical system of dealing with such cases occurring among the poor.

There are two chief obstacles in dealing with these cases: first, the difficulty of obtaining early information as to the disease; and secondly, the difficulty of continuous treatment. The former can be, and is now, reduced by the Midwives Act, 1902, which brings the supervision of the work of the midwives under the control of the local sanitary authority, and by impressing on midwives the serious nature of even the slightest appearance of inflammation in the eyes and the need for prompt medical attention. In order to accentuate these lessons particulars have been supplied by Mr. Walker of any cases of ophthalmia neonatorum which from time to time come under his notice, and the midwife who attended the confinement is interviewed and dealt with as the circumstances of the case require. The Notification of Births Act also assists in bringing cases of the disease to light, but it is not as effectual as the Midwives Act.

As regards continuous treatment Mr. Walker rightly recognised the immense importance of cases which are too poor to be treated satisfactorily at their homes, being admitted into hospitals together with the mother, and when he was able to arrange for a ward to be set apart for the reception of these cases in St. Paul's Eye and Ear Hospital, the health department willingly afforded the assistance of an ambulance for the purpose of conveying the mother to the hospital in order that the infant might not suffer in being separated from the mother. The results of this experiment have been so encouraging as to make us hope that it may be the means of bringing this affection, which is followed at present by so much misery, into greater prominence, and of developing a system for its prevention and treatment which will further reduce the number of preventable cases of blindness in our hospitals and asylums.

Liverpool.

THE RIBERI PRIZE.—The Riberi prize, which is worth 20,000 francs and which is awarded by the University of Turin once every five years, has been gained by Professor Bartolomeo Gosto, one of the directors of the Public Health Laboratory of Rome, for his researches on the "Bio-reactions of Arsenic, Tellurium, and Radium."

THE TREATMENT OF TRACHOMATOUS DACRYOCYSTITIS.

BY T. HARRISON BUTLER, M.D. OXON., M.R.C.S. ENG.,
HONORARY OPHTHALMIC SURGEON TO THE COVENTRY AND WARWICKSHIRE HOSPITAL; LATE ASSISTANT SURGEON TO THE BRITISH OPHTHALMIC HOSPITAL, JERUSALEM.

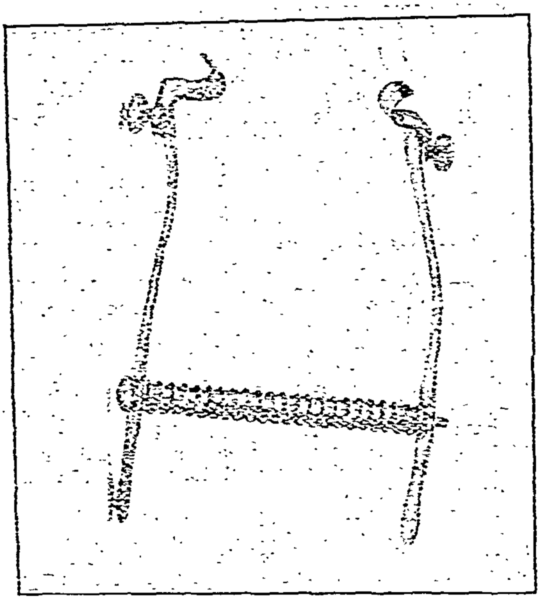
WHEN I first began to treat cases of lacrymal obstruction in Palestine I was surprised to find that they reacted to treatment very differently from similar cases in Europe. The average Arab's or Oriental Jew's eye (I do not here include the imported Polish Jew) will tolerate very much more intra-ocular manipulation than will the Western's eye; for example, one can needle without fear of any subsequent reaction and post-operative iritis is never seen in Jerusalem, if even reasonable cleanliness be observed. With regard to the lacrymal apparatus conditions are reversed: treatment which may in England be adopted with impunity in the East can lead to disaster.

It has for a long time been my custom to treat lacrymal obstruction by daily lavage with Anel's syringe. I use solution of normal saline or boric acid, and if any mucoid discharge be present I leave a few drops of a 5 per cent. solution of protargol in the sac. I have carried out this method constantly in England and I have never seen a single case in which it caused irritation. In Jerusalem simple syringing has in my hands caused œdema of the lids and now and then a regular "black eye." On several occasions the syringeful of lotion, instead of entering the nose or returning by the canaliculi, has distended the loose tissues of the lower lid. In two cases of suppurative dacryocystitis, one of them under the care of a colleague, an eye was lost through a retrobulbar abscess followed by optic atrophy. The injection of protargol in any solution stronger than 5 per cent., or of a ½ per cent. solution of silver nitrate invariably caused œdema and great pain.

All these patients suffered from trachoma, often in a severe form, and I have come to the conclusion that the sacs and canaliculi were also trachomatous and were in consequence very friable. The slightest pressure appeared to cause a rupture of the sac walls and the fluid then passed into the surrounding tissues. These trachomatous sacs are often of enormous size; I remember two which when dissected out were as large as pigeons' eggs; the walls are very thick and yet so friable that it is almost impossible to remove them intact. Basso[1] has demonstrated the existence of a trachomatous dacryocystitis, and he points out that such a condition may be the sole manifestation of trachoma, and, in fact, was so in 14 cases out of the 20 which he examined.

Treatment must be carried out with extreme care, and no stronger solution of protargol or argyrol than 5 per cent. can be safely employed—in fact, it is better to use none at all until the sac has become accustomed to simple lavage with boric acid or normal saline solution. If pus be present it is very much wiser to dissect out the sac at once than to run the risk of causing a retrobulbar abscess. All the cases in which this was done did well, but owing to the prevalence of trachoma and chronic irritation of the lids in the East epiphora is more frequently complained of after extirpation than with us. The operation may be more extensive than usual, for the sac may extend to the middle of the lower eyelid. Hæmorrhage is apt to be very troublesome, but it can be to a certain extent avoided if it be borne in mind that it usually comes from the upper and nasal aspects of the sac. If the dissection be commenced from below and from the outside the sac can often be defined and freed from its attachments before the nasal side is attacked. If possible the angular vein should be located and the skin incision be made external to it; it should not be carried too high up or the branch which comes from the upper lid will be cut. Later in the operation when the sac has been defined the incision can, if necessary, be extended upwards. I rarely use a retractor; a suture through each wound lip held by a nurse is more convenient. Occasionally I use Axenfeld's retractor, which I have modified in the manner well shown in the accompanying illustration. The three sharp prongs of the original, impelled by a powerful spring, seemed to me so very dangerous that I got Messrs. Down Bros. to replace them by a simple curved flat plate. The original fork once wounded my finger and the idea was ever present that the retractor might slip and all three prongs bathed in pus be driven into the cornea. The modified instrument has proved as efficient as the original and is perfectly safe.

I have rarely seen a case cured by the use of probes and styles. The highly fragile and irritable mucous membrane, which is so easily ruptured by simple hydrostatic pressure, is torn and lacerated by a probe, however dexterously passed, and the resulting organic strictures are incurable. In my opinion if a case of dacryocystitis cannot be rapidly cured by simple lavage and protargol the sac should be extirpated.



The following cases illustrate some of the difficulties which have been mentioned:—

CASE 1.—A Jew, aged 55 years, came to the British Ophthalmic Hospital on July 8th, 1903, suffering from dacryocystitis. He was told to attend on the next day for treatment but was not seen again until the 13th. The canaliculus was dilated with Lang's dilator and the sac was irrigated with boric lotion. The sac was full of pus, but the duct was patent, fluid passing freely into the nose. This treatment was repeated on the 15th, 17th, 20th, and 23rd. Each time there was less pus, and there was no sign of any local inflammation after the treatment. The patient did not attend again until the 27th when he appeared with the following condition. The whole eye was pushed forwards, there was great pain, and much brawny œdema of the lids. The lids were hot and the patient had a raised temperature. There was no iritis; the pupil was normal in size but did not react. There was no perception of light. The man was admitted and an incision was made under the brow. Some thick pus was found on the outer side of the orbit and was evacuated by Hilton's method. On the 30th the inflammation was much less and the eye had resumed its normal position. V. = hand reflex, good perception of light; fundus not seen on account of opaque media. On Oct. 30th all was quiet; no perception of light; vitreous full of large floating opacities. The disc was dead white and the arteries were small.

This patient had severe trachoma. Most probably the walls of the sac were ruptured by the syringe and septic matter was forced into the tissues. The pus was found at the outer aspect of the orbit.

CASE 2.—A Jewess, aged 56 years, came to the British Ophthalmic Hospital suffering from trachoma, trichiasis, nebulous cornea, and adherent leucoma. There was a dacryocystitis of ten years' standing. The canaliculus had been slit up and probes had been passed. On June 29th the sac was syringed out with boric acid. On July 8th the sac was syringed out and a few drops of a ½ per cent. solution of silver nitrate were injected and again washed out. On the 9th there was much swelling of the lids with chemosis and great pain. On the 13th a No. 4 Bowman's probe was passed and bare bone was felt. On the 15th the sac was again syringed out and some blood-clot washed out; there was a free passage to the nose. On the 20th the sac was swollen and hard; it extended to the middle line of the lower lid and was probably full of blood. On the 23rd the sac was dissected out. It was as large as a pigeon's egg and its walls were from 1·5 millimetres to 2 millimetres thick. The operation cured the case.

---

[1] Annali di Ottalmologia, vol. xxxv., 1906, fasc. 7-8.

CASE 3.—A female Arab, aged 30 years. This case was almost exactly similar to the last cited. The sac was enormous and contained two drachms of pus; it was syringed out and a little ½ per cent. silver nitrate solution was left *in situ*. This caused great œdema and pain. The sac was syringed out daily for 14 days with no result. A No. 4 probe found a tight stricture and bare bone. The canaliculus was now slit up by a colleague and the neck of the sac was divided with Stilling's knife, a large conical probe was passed into the nose, a counter puncture was made in the skin, and a drain inserted. This treatment had no effect. Ultimately the sac was extirpated and the patient was cured.

Both these patients had old cicatricial trachoma; the sacs were of large size with thick walls. Silver salts were not tolerated.

CASE 4.—A Jew, aged 26 years. On Nov. 10th, 1904, there was a discharge of pus from the left lacrymal sac. The condition was said to have been present for some time but the patient could not say how long. On the 11th the sac was syringed out with boric acid and a few drops of a 10 per cent. solution of protargol were left in the sac. On the 12th the left side of the nose and both lids were œdematous and there was much pain. This œdema cleared up in two days and treatment was continued with 5 per cent. protargol solution which was well tolerated. A month's treatment was without result.

In this case 10 per cent. protargol caused irritation. Parsons[2] recommends that from 10 to 15 per cent. be used, and I have personally often used 15 per cent. in England. In Palestine in trachomatous cases even 10 per cent. is never tolerated.

Coventry.

ON THE PATHOLOGY AND TREATMENT OF INGUINAL HERNIA IN CHILDREN.[1]

BY C. H. FAGGE, M.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON TO GUY'S HOSPITAL; CONSULTING SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK.

OUR ideas on the pathology and treatment of this exceedingly common ailment have been so considerably altered during the last ten years that I think no excuse is necessary in choosing this as the subject for our consideration to-day. I shall found my remarks on 78 patients who were all suffering from inguinal hernia and who were operated upon by me in this hospital; I have purposely excluded my other cases as these, treated in similar circumstances and by the same method, well illustrate the points which in my opinion demand our attention in dealing with hernia in children. In briefly discussing the pathology of this condition I shall ask you to accept the view which was first definitely laid down by Hamilton Russell[2] of Melbourne which states that hernia is primarily a developmental defect owing to either partial or complete persistence of the embryonic processus vaginalis. Russell has expanded his theory so as to include herniæ in all situations and whenever they may appear, and although others hold an opinion contrary to this as to the causation of some herniæ occurring in adults most of those who have given the subject much attention agree with Russell's view in the causation of the condition which we are discussing to-day.

You will remember that in fœtal life a process of parietal peritoneum is pushed or drawn down in front of the descending testicle, and that from this the tunica vaginalis is formed, the remainder of the peritoneal tube in normal circumstances being obliterated. It is a well-accepted view that persistence of the whole process gives rise to what has for a long time been called a "congenital" hernia; it is strange that while this is allowed the presence of a peritoneal process extending from the internal ring along the inguinal canal and yet unconnected with the tunica vaginalis should be regarded as an entirely new formation driven down from above by abdominal pressure. It is surely more logical to admit that while in some cases the processus vaginalis may entirely persist, in others it may do so partially, giving rise to a sac which should bowel or omentum come down into it will produce in a child what was regarded as an acquired inguinal hernia; this will then be more correctly described under the term of partial funicular or congenital hernia. To my mind this is a far easier explanation than to suppose that increased abdominal pressure from flatulence or coughing is associated with a local weakness of the abdominal wall in the inguinal region, which have previously been regarded as factors of primary importance in this connexion. No doubt increased abdominal pressure from flatulence due to improper feeding or from straining due to phimosis may be contributory causes, for it is of course clear that the mere presence of a peritoneal sac does not constitute a hernia unless there is some abdominal viscus which can be made to descend into it. But I want to insist that the primary and chief factor is the patent funicular process, and that it is often present was shown by Murray at the British Medical Association meeting at Exeter in 1907, who reported that in 200 consecutive necropsies 68 potential hernial sacs were found, of which 13 were inguinal; this confirms Sach's investigation upon the bodies of infants at four months when in 59 per cent. of a large number he found this process incompletely closed.

I wish as far as possible to avoid the error of drawing strict statistical deductions from a small number of cases, but in pointing out that in eight only of my 78 cases was the peritoneal process complete I am in agreement with the general opinion that the "total funicular herniæ" form only about 10 per cent. of all cases; Murray, 18 per cent.; Styles, 5 per cent. in 360 cases. In these eight patients the testis was either undescended or could be returned into the canal, and similarly of the seven girls upon whom operation was undertaken the ovary was found in the sac three times.

With regard to the diagnosis, there is only one inguino-scrotal swelling which is likely in a child to give rise to any difficulty and this is a patent processus vaginalis containing fluid, or in other words a "congenital" hydrocele. These swellings are in my experience usually irreducible, though the fluid will spontaneously return into the abdomen when the child has been lying down for a short time. When the fluid returns into the vaginal process it does so slowly and this is in itself quite sufficient to differentiate it from a hernia. In this relation I cannot agree with my former colleague Mr. H. S. Clogg, who in his paper in the *Practitioner* of September, 1907, states that a hernia in a baby may be translucent owing to the thinness of the bowel wall. I was taught that this was so, yet though throughout my seven years as a surgeon here I have systematically investigated this point I have never seen a translucent hernia though I have been called upon to operate upon two or more translucent swellings admitted as herniæ which proved to be hydroceles. I should much like to have the opinion of those present upon this point.

With regard to treatment, I have never convinced myself that circumcision in my hands has had the slightest effect in aiding the cure or even in preventing the enlargement of a hernia, nor should I expect this to be so, for I have never seen in a child the subject of hernia a degree of phimosis sufficient to balloon the prepuce which must surely have resulted if there were so much obstruction to micturition as in any way to influence the descent of a hernia.

With regard to trusses, I think we may look upon the woollen skein as obsolete, and though of course such an appliance can do no harm its use is to be condemned, as when such advice is given to the parents a false sense of security is produced and so further visits to the medical practitioner are postponed with the result that any attempt at efficient treatment is delayed. It is unnecessary to point out that truss treatment must begin as soon as the rupture appears. In a child a well-fitting spring truss covered with rubber must be applied daily before the child is taken from his cot, while the hernial contents are still within the abdomen, and in many cases where the hernia tends to come done at night a light truss must be worn at night also. The difficulty of efficiently carrying this out and of preventing the skin under the truss becoming tender and excoriated is enormous, and while I am very doubtful whether it is never systematically done by the poor I know that even among private patients the details of this treatment are often neglected. A truss must be worn day and night for several years before we can hope that the hernia will not return if the truss is omitted, and during this time great care must be taken that a new truss is obtained so soon as the child outgrows the old one; it is a matter of common experience in all hospital out-patient departments that the parents soon tire of the trouble and expense and allow the hernia to go its own way.

---

[2] Brit. Med. Jour., February, 1907.

[1] A paper read before the Lambeth branch of the British Medical Association at the Evelina Hospital on March 26th, 1908.

[2] THE LANCET, Nov. 18th, 1899, p. 1353, and May 31st, 1902, p. 1519.

McAdam Eccles,[3] who strongly upholds treatment with trusses, is of opinion that this must be carried out for at least three years and holds that until this has failed the operation of radical cure should not be undertaken. One is often asked by private patients what promise there is of cure after careful and persistent truss treatment. I think it is fairly stating the case to say that a truss never cures a rupture but that by preventing its descent, dilatation of the neck of the sac and the secondary dragging downwards and displacement of the posterior wall of the inguinal canal, which should rightly be regarded as complications of the hernia, are avoided; again, the probability of strangulation is much diminished. But that trusses will do more than this I cannot believe. Of all the patients whom as an out-patient surgeon I treated here I can only remember one in whom this treatment had been so consistently carried out that after an interval of two years or more the hernia no longer came down when the patient stood up without the truss. In this connexion it is well to remember Coley's statistics which showed that of 15,000 radical cures in adults 5000, or 33 per cent., had been treated with trusses in childhood. I think it is now the duty of every medical man to impress upon parents that trusses hold out no prospect of permanent cure as the time has certainly arrived when cure can be more easily and almost certainly obtained by operative means which in themselves are practically devoid of risk.

I should regard the following as absolute indications for operation: (1) herniæ which cannot be kept up by trusses or which are painful when a truss is worn; (2) large scrotal herniæ which have stretched the inguinal canal considerably and therefore render trusses necessary throughout life; (3) the association of an undescended testis with an inguinal hernia; and (4) a hernia which has been irreducible on a previous occasion. This does not, of course, include strangulated herniæ, which must be dealt with at once, but refers to those cases in which the only symptom is irreducibility of the hernia yielding within three or four hours to elevation of the buttocks or suspension from the ankles. In my opinion taxis should never be attempted.

With regard to the broader question of operation in other cases, I am entirely in agreement with the opinion given by Mr. F. S. Eve at the meeting of the British Medical Association in 1899, when he stated that he regarded "agreement on the part of the mother to operation after she has had the alternative of prolonged wearing of trusses explained to her" as a general guide for its performance. Though some period after the first dentition is probably the ideal date at which to undertake a radical cure, there is no disadvantage in doing it much earlier and the presence of a large hernia or one which has been irreducible will sometimes demand operation in the first few months of life. Of my own cases the youngest was a month old and 15 were operated on in the first six months, yet none of these met with any immediate or remote harm, and so far as I have been able to discover there have been no recurrences. When strangulation is present the operation is undertaken under the least favourable conditions, yet in the four cases of my series in which this was present all the babies were under a year (it is generally believed that strangulation is most common in very young babies) and all did remarkably well. The experience of many surgeons shows that urgent operations are well borne in small infants, so that the question of age alone cannot be urged as an argument against a radical cure: in my opinion this is a prophylactic operation undertaken in childhood in order to avoid a more elaborate operation in later years. Further, I think that by operating in childhood we can insure a more certain result, as at this date those secondary changes in the neck of the sac and in the posterior wall of the inguinal canal which I alluded to above have not taken place. In private patients it is unnecessary to wean the infant, but when, as in hospital, this is unavoidable it is well to allow two or three weeks to elapse before operation, so that the child may become used to the new diet, as intestinal derangement may seriously jeopardise the life of an infant after this as after any other surgical procedure.

In the whole of my series the same operation has been carried out—viz., an oblique incision along the inner two-thirds of the inguinal canal exposing the aponeurosis of the external oblique which is well defined towards the pubes where its processes form the pillars of the external ring; the aponeurosis is then slit up from the external ring for about an inch—i.e., up to a point over the internal ring. An oblique incision in the same line as that in the skin is now carried through the cremasteric fascia and muscle and through the transversalis fascia, exposing the sac. It is most important to do this cleanly without unnecessary tearing of the coverings of the cord, for traumatism is undoubtedly the most frequent forerunner of sepsis, and if these structures are torn into shreds the resulting bleeding makes the isolation of the sac a matter of some difficulty. When the sac is exposed it is opened and its contents are reduced. This opening of the sac should be made not lower than the middle of the canal, and the edges being taken up with Spencer Wells forceps the sac is separated from all the other structures, which are carefully displaced in one layer. Here, again, it is important not to separate the coverings layer by layer, as doing so can only interfere with their blood-supply and favour suppuration. The sac is now divided and ligatured at the level of the internal ring with catgut applied in the form of a Staffordshire knot, the sac being meanwhile well pulled down and held taut by an assistant.

When the neck of the sac is being defined and ligatured it is well to remember that it may be encroached upon by the bladder which is here uncovered by peritoneum; similarly the non-peritoneal surfaces of the cæcum on the right or of the iliac colon on the left may slide down into the neck of the sac, forming a hernia *en glissade*. The possibility of the involvement of these structures must be borne in mind and the operator must convince himself both by sight and by touch that the neck of the sac is quite free before the ligature is applied. The external oblique aponeurosis is now sewn up beginning below at the external ring which if enlarged is narrowed so as just to allow room for the passage of the cord. In some of my earlier operations on children over six years of age one or more sutures were passed through the conjoint tendon so as to bring it down to Poupart's ligament after the method of Bassini, but I am convinced that this is unnecessary and have given it up, for in children the conjoint tendon is so strong and grips the internal ring like a sphincter in a manner which the surgeon cannot hope to improve upon. The wound having been sutured a sealed dressing is applied which is not touched until the eighth day, when the superficial suture is removed. The nursing of these patients is important; at this hospital they were placed on a mattress so divided that its middle third was replaced by a bedpan covered with a rubber air cushion which in small babies prevents soiling of the back and the possibility of excoriation of the skin; the penis was secured into the neck of a test-tube leading to a bottle so that the urine is carried well away from the region of the wound.

With regard to my results, none of the children were seriously affected by the operation but two contracted scarlet fever and were sent away; a third, aged two years, left the hospital with measles and is reported to have died at home; two cases suppurated which necessitated their retention in hospital for at least a fortnight more than was usual but in neither did this have any influence upon the ultimate result. The average stay in hospital was from 10 to 14 days and so far as I can judge there have been no recurrences, though I have seen and examined a large majority in the out-patient department at periods varying from six months to two years after operation. If it is true, as many hold, that recurrence is most likely within one year of operation then most of my cases have escaped during the period of greatest danger, but it is certainly too soon to label them as cures.

Time does not permit of prolonged consideration of the treatment of an undescended or misplaced testis complicating hernia which occurred in eight of my cases, but I must say that in my experience this condition is absolutely unfitted for a truss which usually cannot be applied because of the presence of the testis in the canal, or if a truss is worn above the testis pain from stretching of the cord is often so severe that it must be omitted. These considerations and the fact that an undescended testis is so often in the life of an active boy exposed to nipping and other painful injuries have led me to regard this as in itself a definite indication free passage to the nose. On the 20th the sac was swollen and hard; it extended to the middle line of the lower lid and was probably full of blood. On the 23rd the sac was dissected out. It was as large as a pigeon's egg and its walls were from 1·5 millimetres to 2 millimetres thick. The operation cured the case.

---

[3] Hernia, 1908.

CASE 3.—A female Arab, aged 30 years. This case was almost exactly similar to the last cited. The sac was enormous and contained two drachms of pus; it was syringed out and a little ½ per cent. silver nitrate solution was left *in situ*. This caused great œdema and pain. The sac was syringed out daily for 14 days with no result. A No. 4 probe found a tight stricture and bare bone. The canaliculus was now slit up by a colleague and the neck of the sac was divided with Stilling's knife, a large conical probe was passed into the nose, a counter puncture was made in the skin, and a drain inserted. This treatment had no effect. Ultimately the sac was extirpated and the patient was cured.

Both these patients had old cicatricial trachoma; the sacs were of large size with thick walls. Silver salts were not tolerated.

CASE 4.—A Jew, aged 26 years. On Nov. 10th, 1904, there was a discharge of pus from the left lacrymal sac. The condition was said to have been present for some time but the patient could not say how long. On the 11th the sac was syringed out with boric acid and a few drops of a 10 per cent. solution of protargol were left in the sac. On the 12th the left side of the nose and both lids were œdematous and there was much pain. This œdema cleared up in two days and treatment was continued with 5 per cent. protargol solution which was well tolerated. A month's treatment was without result.

In this case 10 per cent. protargol caused irritation. Parsons[2] recommends that from 10 to 15 per cent. be used, and I have personally often used 15 per cent. in England. In Palestine in trachomatous cases even 10 per cent. is never tolerated.

Coventry.

ON THE PATHOLOGY AND TREATMENT OF INGUINAL HERNIA IN CHILDREN.[1]

BY C. H. FAGGE, M.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON TO GUY'S HOSPITAL; CONSULTING SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK.

OUR ideas on the pathology and treatment of this exceedingly common ailment have been so considerably altered during the last ten years that I think no excuse is necessary in choosing this as the subject for our consideration to-day. I shall found my remarks on 78 patients who were all suffering from inguinal hernia and who were operated upon by me in this hospital; I have purposely excluded my other cases as these, treated in similar circumstances and by the same method, well illustrate the points which in my opinion demand our attention in dealing with hernia in children. In briefly discussing the pathology of this condition I shall ask you to accept the view which was first definitely laid down by Hamilton Russell[2] of Melbourne which states that hernia is primarily a developmental defect owing to either partial or complete persistence of the embryonic processus vaginalis. Russell has expanded his theory so as to include herniæ in all situations and whenever they may appear, and although others hold an opinion contrary to this as to the causation of some herniæ occurring in adults most of those who have given the subject much attention agree with Russell's view in the causation of the condition which we are discussing to-day.

You will remember that in fœtal life a process of parietal peritoneum is pushed or drawn down in front of the descending testicle, and that from this the tunica vaginalis is formed, the remainder of the peritoneal tube in normal circumstances being obliterated. It is a well-accepted view that persistence of the whole process gives rise to what has for a long time been called a "congenital" hernia; it is strange that while this is allowed the presence of a peritoneal process extending from the internal ring along the inguinal canal and yet unconnected with the tunica vaginalis should be regarded as an entirely new formation driven down from above by abdominal pressure. It is surely more logical to admit that while in some cases the processus vaginalis may entirely persist, in others it may do so partially, giving rise to a sac which should bowel or omentum come down into it will produce in a child what was regarded as an acquired inguinal hernia; this will then be more correctly described under the term of partial funicular or congenital hernia. To my mind this is a far easier explanation than to suppose that increased abdominal pressure from flatulence or coughing is associated with a local weakness of the abdominal wall in the inguinal region, which have previously been regarded as factors of primary importance in this connexion. No doubt increased abdominal pressure from flatulence due to improper feeding or from straining due to phimosis may be contributory causes, for it is of course clear that the mere presence of a peritoneal sac does not constitute a hernia unless there is some abdominal viscus which can be made to descend into it. But I want to insist that the primary and chief factor is the patent funicular process, and that it is often present was shown by Murray at the British Medical Association meeting at Exeter in 1907, who reported that in 200 consecutive necropsies 68 potential hernial sacs were found, of which 13 were inguinal; this confirms Sach's investigation upon the bodies of infants at four months when in 59 per cent. of a large number he found this process incompletely closed.

I wish as far as possible to avoid the error of drawing strict statistical deductions from a small number of cases, but in pointing out that in eight only of my 78 cases was the peritoneal process complete I am in agreement with the general opinion that the "total funicular herniæ" form only about 10 per cent. of all cases; Murray, 18 per cent.; Styles, 5 per cent. in 360 cases. In these eight patients the testis was either undescended or could be returned into the canal, and similarly of the seven girls upon whom operation was undertaken the ovary was found in the sac three times.

With regard to the diagnosis, there is only one inguino-scrotal swelling which is likely in a child to give rise to any difficulty and this is a patent processus vaginalis containing fluid, or in other words a "congenital" hydrocele. These swellings are in my experience usually irreducible, though the fluid will spontaneously return into the abdomen when the child has been lying down for a short time. When the fluid returns into the vaginal process it does so slowly and this is in itself quite sufficient to differentiate it from a hernia. In this relation I cannot agree with my former colleague Mr. H. S. Clogg, who in his paper in the *Practitioner* of September, 1907, states that a hernia in a baby may be translucent owing to the thinness of the bowel wall. I was taught that this was so, yet though throughout my seven years as a surgeon here I have systematically investigated this point I have never seen a translucent hernia though I have been called upon to operate upon two or more translucent swellings admitted as herniæ which proved to be hydroceles. I should much like to have the opinion of those present upon this point.

With regard to treatment, I have never convinced myself that circumcision in my hands has had the slightest effect in aiding the cure or even in preventing the enlargement of a hernia, nor should I expect this to be so, for I have never seen in a child the subject of hernia a degree of phimosis sufficient to balloon the prepuce which must surely have resulted if there were so much obstruction to micturition as in any way to influence the descent of a hernia.

With regard to trusses, I think we may look upon the woollen skein as obsolete, and though of course such an appliance can do no harm its use is to be condemned, as when such advice is given to the parents a false sense of security is produced and so further visits to the medical practitioner are postponed with the result that any attempt at efficient treatment is delayed. It is unnecessary to point out that truss treatment must begin as soon as the rupture appears. In a child a well-fitting spring truss covered with rubber must be applied daily before the child is taken from his cot, while the hernial contents are still within the abdomen, and in many cases where the hernia tends to come done at night a light truss must be worn at night also. The difficulty of efficiently carrying this out and of preventing the skin under the truss becoming tender and excoriated is enormous, and while I am very doubtful whether it is never systematically done by the poor I know that even among private patients the details of this treatment are often nerves. Fig. 1 is a reproduction of a micro-photograph of a transverse section of the optic nerve stained according to Weigert's method. The central part is pale and presents the changes of a typical sclerosed patch; the peripheral part (dark) is normal. Medullated nerve fibres are almost absent in the centre of the section (sclerosed patch), but are present at the periphery. Fig. 2 represents a drawing of a transverse section of the optic chiasma, most of which is occupied by a sclerosed patch. The section was stained according to Weigert's method and normal (black) fibres were seen only at the periphery of the section.

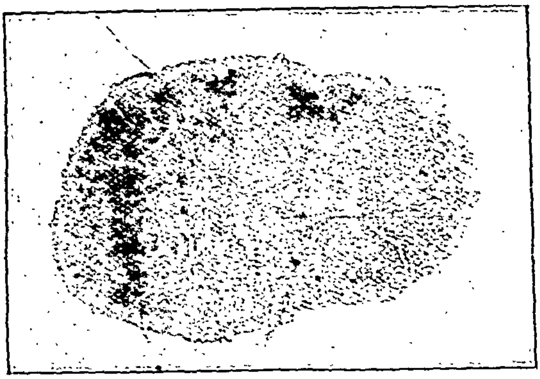
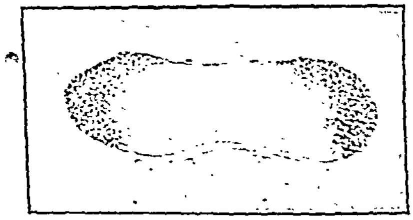
FIG. 1.



Reproduction of a micro-photograph of section of optic nerve. Weigert's stain. Sclerosis (pale) in the centre.

FIG. 2.



Optic chiasma, transverse section. Weigert's stain. Pale area (sclerosis) in the centre. (× three diameters.)

In the form of disseminated sclerosis beginning with visual failure pain and anæsthesia are very rare, as in other forms of this disease. The signs of chief diagnostic value at the early stage are: (1) unilateral or bilateral visual failure, with central scotoma in some cases and often with pallor of the optic disc, especially of the temporal half; (2) the Babinski type of plantar reflex on one or both sides; (3) the irregular and shaky character of the handwriting, even when the tremor is so slight that it can hardly be detected (a most valuable sign); and (4) the age of the patient, under 40 years. The absence of any cause for the affection and of any history of syphilis, the absence of pain and anæsthesia, and the presence of the knee-jerks, tendo Achillis reflexes, and pupillary reflexes are points of diagnostic value in favour of disseminated sclerosis. It is interesting to note that in many cases after the visual defect has become marked there is a decided improvement or almost complete recovery of vision. In other cases the visual defect remains more or less stationary, and when it does progress it very rarely advances to complete blindness, in this respect differing from the optic atrophy of tabes dorsalis.

It is also interesting to note that though the prognosis of disseminated sclerosis is usually unfavourable and the termination fatal, still statistics show that in many cases the course of the disease is very chronic—the duration being from 10 to 20 years or more. Often the disease remains stationary for a long period, remissions of long duration sometimes occur, and occasionally there is apparent recovery. (Cases of apparent recovery have been recorded by Charcot, Marie, Oppenheim, Maas, Byrom Bramwell, and others.) These facts encourage the hope that in the future some treatment will be discovered which will be of distinct service in checking the progress of the disease.

Manchester.

ON THE RECTAL ADMINISTRATION OF ANTITOXIC SERA.

By J. PORTER PARKINSON, M.D. LOND., F.R.C.S. ENG.,
PHYSICIAN AT THE QUEEN'S HOSPITAL FOR CHILDREN AND AT THE LONDON TEMPERANCE HOSPITAL.

IT is now more than six years ago since I first published an account of the method of administering certain sera by the rectum and of the advantages of such a method over their subcutaneous injection. This practice had then been successfully followed by my colleagues and myself for several years. My reasons for publishing an account of the method were at that time purely clinical. They consisted in the fact that rapid improvement resulted from the injection, too rapid and too frequent, indeed, to be accounted a mere coincidence. Then the rectal injections are never followed by any of those untoward accidents which are occasionally seen after subcutaneous injections. And finally, those patients who object to a prick of the skin as being of the nature of an operation will as a rule submit to rectal medication. Since that paper was written many others have used the method and some have recorded their successful cases, so that now it rests on a more sure basis. Still some, chiefly those of a physiological and experimental turn of mind, have objected to it, stating that the serum is not absorbed by the rectum. This may or may not be the case, but it has never been contended that it was absorbed in that portion of the bowel but merely that good effects followed rectal injections.

The address in surgery at the meeting of the British Medical Association in 1905 on Ascending Currents in Mucous Canals contains some very interesting facts showing that substances placed in the rectum may pass upwards and may be found in the ascending colon, or even higher in the bowel. In a case of colotomy it was found that when a carmine suppository was placed in the rectum the gauze dressing of the wound was stained by the pigment within 24 hours; the same was found in other cases. They show that an upward current is present while the downward peristalsis is going on at its normal rate. That an excess of this may occur in pathological states has long been known from the vomiting of fæces, which is an occasional symptom of hysteria. Such facts show that if sera are not absorbed by the rectum itself it is not necessary that they are therefore inert, as they may be carried to parts of the bowel where it is not denied that absorption occurs. Lately, however, further evidence has been brought forward to show that sera and similar fluids are absorbed by the rectum and other parts of the large intestine. Calmette and Bretonin in a recently published article[1] show that tuberculin is absorbed by the mucous membrane of the rectum and that the characteristic reaction occurs as quickly and as certainly when the test is injected rectally as when the subcutaneous injection is given. Breton and Petit[2] have shown that tetanus antitoxin is absorbed, as they have immunised guinea-pigs against a poisonous dose of tetanus poison by the rectal injection of the antitoxin. Breton and Massol[3] have shown that both the poison of the cobra and its antitoxin are absorbed by the mucous membrane of the large intestine. Finally, Fornario[4] finds that guinea-pigs, which frequently die during the course of immunisation against the plague, are readily immunised by rectal injections, and the mortality from this is practically *nil*, while the protection is equal to that obtained by the hypodermic method. Taking these experiments of different observers in conjunction with the clinical results it seems that there is not much room for doubt that antitoxic sera are really absorbed when administered by the rectum and that this is an easy channel for their injection.

Up to the present I have hesitated to inject anti-diphtheritic serum otherwise than hypodermically, as I have thought that absorption might be more rapid in that way; but in one very severe case of diphtheria where the family strongly objected to the hypodermic injection the improvement after the rectal injection of the antitoxin seemed to be for operation, though I have not found that bringing the organ down and fixing it in the scrotum has had any beneficial influence upon its growth. In one case in which the defect was bilateral the testes were returned into the abdomen but in all the others the organ was brought down into the scrotum and secured by a suture passed through the skin.

Devonshire-place, W.

DISSEMINATED SCLEROSIS, COMMENCING WITH FAILURE OF VISION.

BY R. T. WILLIAMSON, M.D. LOND., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, ROYAL INFIRMARY, AND LECTURER IN MEDICINE, VICTORIA UNIVERSITY, MANCHESTER.

DURING recent years many forms of disseminated sclerosis have been described; but the form considered in this article is not well known and very often it is not diagnosed correctly at first. In this form failure of vision, in one or both eyes, is the first symptom of the disease. Other symptoms may not appear or may be only very slight for a long period, even for many years. It is well known that optic atrophy, and especially partial atrophy with pallor of the temporal half of the optic disc, occurs during the course of many cases of disseminated sclerosis. But Oppenheim, Müller, and others have drawn attention to a form of disseminated sclerosis in which visual failure, with or without signs of optic atrophy, is the first symptom, and sometimes the only symptom for a long period or for several years. Optic atrophy is sometimes one of the earliest signs of tabes, and failure of vision the first symptom for which the patient seeks advice. Likewise in disseminated sclerosis, visual failure, from changes in the optic nerve or chiasma, may be the first symptom of the disease or the first symptom to attract attention. At first these cases are usually diagnosed as primary optic atrophy, or as retrobulbar neuritis, of "unknown origin." In all such cases it is important to watch for symptoms of disseminated sclerosis.

E. Müller[1] states that in a young person who has never suffered from syphilis, lead poisoning, or alcoholism, if amblyopia should suddenly develop in one eye and then partially subside, and if some time later a similar affection should develop in the other eye, the diagnosis of disseminated sclerosis is very probable. In such a case confirmatory signs would be—pallor of the temporal half of the optic disc, with the characteristic relations of the field and defect of vision, failure of the abdominal reflexes, the Babinski extensor type of plantar reflex, and slight shaking of the hands on fine movements. The age of the patient (from 20 to 40 years), the absence of any recognisable cause, the absence of pain (in most cases), and the satisfactory general condition would be points in favour of the diagnosis of disseminated sclerosis. The following are notes on cases of this form of the disease.

CASE 1.—The patient, a married woman, aged 33 years, came under treatment on account of failure of vision and unsteadiness in walking. About three and a half years before she was first seen the vision for distant objects had commenced to fail. *At that time no other symptoms were noticed.* A year and a half later she was confined, and a few months afterwards *she noticed unsteadiness* in walking and numbness of the hands. When first seen, at the end of 1906, *the chief symptoms* were unsteadiness in walking, staggering gait, nystagmus, slight intention tremor of the hands, and failure of vision. The distant vision was $\frac{6}{18}$ (both eyes), the optic discs were pale and atrophic, and colour vision was impaired at the centre of the field. The knee-jerks were increased; there was no ankle-clonus; the plantar reflexes were of the normal form. There was only the slightest tendency to the "scanning" character of the speech. In February, 1907, the gait was more unsteady. The knee-jerks were increased, there were ankle-clonus and the extensor (Babinski) form of plantar reflex on the right side but not on the left. The abdominal and epigastric reflexes were absent, the wrist-jerk and triceps-jerk were increased on both sides, and there was a well-marked radial extensor jerk on the right side but not on the left. An ulnar extensor jerk was present on both sides. There was a little intention tremor in the hands and the writing was very irregular. There was distinct nystagmus, but the *affection of speech* was very slight. The distant vision was: right, $\frac{6}{18}$; left, $\frac{6}{24}$. The optic discs were very pale and presented the changes of primary atrophy.

CASE 2.—The patient was a married woman, aged 27 years. About two and a half years before the patient came under treatment *vision began to fail* in the right eye and in three weeks was almost lost. Then improvement occurred *gradually until the vision* became almost normal. She was seen by an ophthalmic surgeon at the time, and "an affection *of the optic nerve behind* the eye-ball" was diagnosed. About 18 *months later*—i.e., *about four months before* she came *under my observation*—she first noticed unsteadiness in walking. When examined (September and October, 1906) the *chief symptoms* and *signs* were: ataxic gait; knee-jerks present; extensor type of plantar reflex (Babinski's reflex) and *Oppenheim's reflex on the right side*, but not on *the left*; vision: left eye, $\frac{6}{6}$ partially; right eye, $\frac{6}{6}$, and the right optic *disc* rather pale. *In March, 1907*, the ataxia had disappeared. The condition of reflexes was the same. Vision, left eye, $\frac{6}{6}$ partially; *right eye*, $\frac{6}{12}$.

CASE 3.—The patient, an unmarried woman, aged 36 years, *was seen first in September, 1904.* Six weeks *previously* her vision had failed markedly in the right eye without any apparent cause. *Ophthalmoscopic examination* had failed to reveal any change. The vision had greatly improved when I *first* saw her, *but the disc* had become pale. For two weeks there had been unsteadiness in walking. Examination *revealed only* the following symptoms and signs: pupils unequal, left larger than right, both reacted to light; vision:—right *eye*, $\frac{6}{9}$ partially; left eye, $\frac{6}{6}$ partially; right optic disc pale, left normal; Babinski's extensor *type of* plantar reflex on the right side; slight nystagmus; knee-jerks present; no ankle-clonus. The patient improved and considered that she had completely recovered, but in December, 1906, she commenced to drag the right leg in walking. This symptom steadily increased and she noticed that there was a tendency to scrape the toes of the right foot and that the leg was becoming weaker. There was also slight intention tremor in the right arm. On examination in February, 1907, there was spastic paresis of the right leg. The knee-jerks were increased. There was definite ankle-clonus, and the Babinski or extensor type of plantar reflex on the right side but not on the left. The handwriting was very irregular and jerky. The wrist-jerk on the right side was much greater than on the left. There were an ulnar extensor jerk and a radial *extensor* jerk on the right side but not on the left. Vision: *right eye*, $\frac{6}{12}$; *left* eye, $\frac{6}{6}$ partially; both optic discs were pale. In March, 1907, the vision = right eye, $\frac{6}{12}$; left eye, $\frac{6}{9}$. Ankle-*clonus* and the Babinski form of plantar reflex were present on the right side. The handwriting was much more irregular and jerky.

CASE 4.—The patient was a female, aged 29 years. When a girl about the age *of* 12 *or* 13 years vision failed in the left eye. She was treated at an ophthalmic hospital and disease of the left optic nerve was diagnosed. There were no symptoms of intracranial disease and no cause for the affection of the vision could be detected. In the course of several months the vision gradually improved. At the age of 26 years she began to drag the right leg in walking; in course of time the left leg became affected and the loss of power gradually increased. When first seen (in 1902) there was marked nystagmus with *spastic* paraplegia. There was rigidity of the legs on passive movement with marked loss of power; the knee-jerks were both increased, ankle-clonus and the Babinski type of plantar reflex were present on each side. There was slight intention tremor of the right hand and the writing was jerky and irregular. The nystagmus was so marked and persistent that it was quite impossible to see the optic discs.

CASES 5 AND 6.—In two *other cases* which I had the opportunity of examining frequently, many years ago, visual failure from optic atrophy was the first symptom of the disease. *Both cases terminated* fatally and the spinal cords were given to me for pathological examination. I found the typical changes of disseminated sclerosis in both cases. In one case *failure of vision* in one eye, the first symptom, was noticed more than five years before the fatal termination. Six months after the onset of the visual failure spastic paraplegia commenced to develop. Nystagmus and the typical *symptoms* of the disease followed. Optic atrophy developed on both sides. In the spinal cord and brain I found, on microscopical examination, numerous typical patches of disseminated sclerosis. There was also a patch of *sclerosis affecting* the greater portion of the transverse section of the optic chiasma, and sclerosed patches were present *in the optic* case, which differed in so many details from the ordinary description of this rare disease, certainly did not confirm this hypothesis. The man's occupation threw no light on his condition. I might also add that there was no history of lead colic and no symptom suggestive of lead or any other chemical poison. The chilblains from which the patient had suffered in winter time before could not be the cause of the "œdema."

---

[1] Neurologisches Centralblatt, No. 13, 1905.

The *fons et origo* of the patient's illness is difficult to fathom. As a possible solution of the problem of diagnosis I should be inclined to suggest that the "œdema" was due to some disturbance of the normal vaso-motor mechanism. As regards the drug treatment of the case the mixture of iodide and mercury seemed to have some beneficial effect.

St. Mary Cray.

A CASE OF SUBCLAVICULAR DISLOCATION OF THE HUMERUS.

By WILLIAM BOURNE HALLOWES, L.R.C.P., L.M., L.R.C.S. IREL.,

SENIOR SURGEON, NEWARK HOSPITAL; CERTIFYING FACTORY SURGEON, NEWARK DISTRICT; MEDICAL OFFICER TO THE POST OFFICE.

THE rarity of the above injury is my reason for placing it on record.

The patient, a burly Scotsman, about 15 stones in weight, came to see me one evening some few months ago stating that he thought his right shoulder "was out." He told me that on the same afternoon he was riding in a tram at Lincoln, when suddenly discovering that he was being taken farther than he wanted to go he jumped up and left the car while it was going rapidly; at the time he was carrying two parcels on his left arm. He said that he was thrown violently forwards but was unable to state accurately how his right hand came in contact with the ground. However, a lacerated wound over the thenar eminence seemed to indicate that, owing to the impetus given to him by the car, his right arm as he fell was extended in an outward and backward direction when his hand struck the ground. On removing his clothes a glance sufficed to verify his diagnosis, extreme flattening of the deltoid, marked prominence of the acromion, and a deep sulcus over the glenoid cavity (into which three or four fingers could be pressed with ease) indicating the absence of the head of the humerus from its normal position. Closer investigation and palpation revealed the fact that the head of the humerus was not in the axilla, neither could it be felt by careful examination in that region. A globular swelling situated below the middle and outer third of the clavicle, the shaft of the humerus pointing in the most marked manner outwards and somewhat backwards, and complete inability to approximate the elbow to the side, proved beyond doubt that the case was one of those so rarely met with—viz., complete subclavicular dislocation of the humerus.

Placing the patient flat on his back and flexing the elbow-joint I firmly gripped the lower end of the humerus and applied extension downwards, my object being to clear the coracoid when the time came for employing rotation outwards. After a few minutes' extension, gradually applied with increasing strength, the globular swelling had considerably moved downwards from its position immediately below the clavicle; then suddenly rotating outwards, followed instantly by bringing the arm sharply across the chest, I had the satisfaction, at the second attempt, of feeling and hearing the head of the bone slip back into its normal position. Considerable swelling of the parts in the vicinity of the joint followed the reduction, and a well-marked globular ecchymosis indicated for several days the position occupied by the head of the humerus immediately below the middle and outer third of the clavicle. The limb was placed in a triangular bandage. On the following morning passive movements were commenced and cautiously increased day by day, the patient being exhorted to use great care in gradually resuming the usual movements of the joint and limb, which instructions he faithfully carried out until complete recovery resulted.

Bryant[1] gives an illustration of this injury and says: "Subclavicular dislocations in which the head of the humerus rests below the clavicle on the sternal side of the coracoid process are exceedingly rare. I have never seen a complete example." Lower down in the same paragraph he says: "The bulk of cases recorded as of the subclavicular kind are probably subcoracoid." Rose and Carless[2] say: "The subclavicular variety is very uncommon and merely an exaggeration of the subcoracoid, the head of the humerus passes further inwards and lies deeply under the pectoralis major, on the second and third ribs." Keen and White,[3] under the head of anterior dislocation, say: "These present two varieties, the subcoracoid and the intracoracoid, according to the distance to which the head of the humerus is displaced inwards. An extreme form of the latter is sometimes called the subclavicular."

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Tuberculosis of the Fallopian Tube.—Cæsarean Hysterectomy.—Excretion of Creatinin.—Intra-uterine Death of the Fœtus.

A MEETING of this section was held on April 9th, Dr. HERBERT R. SPENCER, the President, being in the chair.

Dr. H. MACNAUGHTON-JONES read a short communication on the subject of Primary Unilateral Tuberculosis of the Fallopian Tube. He briefly reviewed the more recent etiological and histological points bearing on tuberculosis of the female genitalia, dealing with the relative frequency with which the various organs are affected from the vulva to the ovary. The occurrence of primary tuberculosis in any of the genitalia was not common but a unilateral primary tuberculosis was very rare. His communication dealt with primary unilateral tuberculosis of the Fallopian tube, of which he had met with two instances, and he had one case of primary tuberculosis of both tubes. In all these the rest of the genitalia were healthy. The details of the three cases were given and all the removed tubes were shown, together with the microscopical sections. In the case which was the source of this communication a tuberculous pyosalpinx was removed six and a half years ago. The patient had had one twin pregnancy and three other pregnancies since. He had recently to perform on this patient a cœliotomy, 39 days after labour, for an extensive septic perimetritis (the section of the matted adnexa was shown with the epidiascope). There was no evidence of tubercle. She was now perfectly well. All the five children were strong and healthy. Mr. J. H. Targett and Dr. Cuthbert Lockyer had made the reports. He (Dr. Macnaughton-Jones) had received replies from some 35 leading gynæcologists in the United Kingdom and abroad before bringing the case forward as to the records of such a condition. Only in seven of the home clinics were there records of such a lesion and in but three of the foreign.

Dr. KEDARNATH DAS of Calcutta communicated a short paper on Three Cases of Cæsarean Hysterectomy for Atresia of the Vagina which was read by the honorary secretary. Traumatism during labour in which instruments were used was the cause of the condition in each case. Two of the cases were complicated with vesico-vaginal fistulæ which had resisted attempts to close them, although in one case a recto-vaginal fistula had been closed. In the first case the mother died, probably from the infection of the peritoneum through the vesico-vaginal fistula. In this case the child lived. In the second case the mother lived but a dead fœtus was removed from the uterus. In the third case both mother and child lived. Vesico-vaginal fistula was frequent in India. The occurrence of conception in such peculiar circumstances was worthy of note.

Dr. O. J. NEPEAN LONGRIDGE read a short communication on the Creatinin Excretion of Lying-in Women during the most active period of involution of the uterus. The paper was based on 90 estimations of creatinin and 180 estimations of the total nitrogen in the urine. The patients were delivered in Queen Charlotte's Lying-in Hospital and were kept upon a creatinin-free diet during the time they were under observation. The endogenous creatinin alone was estimated.

as rapid and thorough as if it had been given in the ordinary way.

I will conclude by mentioning one case, not an exception, but a type of many others, in which the rectal injection of polyvalent anti-streptococcus serum gave a rapid result in a case of chronic gonorrhœal infection. A man, aged 28 years, came to the out-patient department of the hospital suffering from pains in several joints and especially of severe pain in the heel. He had been infected with gonorrhœa some months previously and still had a slight urethral discharge. I injected 25 cubic centimetres of polyvalent anti-streptococcus serum per rectum and prescribed no other treatment. He went home and when I saw him the following week all his symptoms had gone and there was no visible urethral discharge. He informed me that the pain in the heel, which was his chief trouble, went away within 24 hours after the injection. I should have mentioned that the patient had been under treatment elsewhere for three weeks before he consulted me.

The technique of the injections is extremely simple. It is not necessary to give a cleansing enema without there is much constipation. The patient lies on the left side on a couch and a No. 6 Jacques catheter is passed as far as possible into the rectum; to the catheter is attached the barrel of a glass urethral syringe into which the serum is poured; as a rule gravity is sufficient, but if the fluid does not flow readily the piston can be used in the ordinary way. After the injection the patient should be kept lying on the couch for a quarter of an hour and then can be sent home in a vehicle. Rest in bed is not necessary after the injection, but exertion should not be allowed.

A CASE OF POISONING BY BROMIDE OF POTASSIUM

By A. CAMPBELL STARK, M.B., B.S. LOND.,

LATE DEMONSTRATOR ON MATERIA MEDICA AT ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.

POISONING by bromide of potassium is of sufficiently rare occurrence to make any well-marked example of it worth recording. The following case also presents some features of peculiar interest. The subject was a woman, aged 35 years. She was nearly nine months pregnant. She was of a neurotic temperament but otherwise perfectly healthy. She had suffered from facial neuralgia and was ordered one evening a six-ounce mixture containing 30 grains of bromide of potassium in the ounce. This she placed under her pillow and helped herself to at short intervals during the night. It was afterwards found that she had a private store of the drug which she also took, so that she swallowed altogether about four and a half drachms of the salt in less than 12 hours. When seen on the following day she was in a very drowsy and semi-comatose condition. She could be aroused by speaking loudly to her and answered —apparently without understanding the question—in a hesitating and tremulous manner but was unable to express herself intelligently on account of aphasia. This was extremely well marked and but for the history and the absence of other symptoms would have strongly suggested a cerebral lesion. Thus the medicine was referred to as soup, pastry, as cushion, and so on. She seemed conscious that she was using the wrong word and after several repetitions of it would relapse into silence. Left to herself she passed at once into a semi-comatose state. The respirations were deep, regular, and slightly stertorous, but not slower than normal. The pupils were normal in size and reacted well to light and to accommodation. The pulse was 76, quite regular, and of good volume and tension. The fœtal heart could be heard quite plainly. The knee-jerks were exaggerated and although the muscular movements were slow and feeble the patient was able to leave her bed without assistance and totter about the room. There was no anæsthesia of the skin or mucous membranes and she took food readily and with apparent appetite. These conditions continued without any change for two days. On the third day the aphasia had begun to disappear and by the end of the fourth day the patient was practically well. She had no recollection of what had happened during the first two days. No treatment was adopted except the administration of five-minim doses of liquor strychninæ every four hours. Three weeks afterwards the patient gave birth to a vigorous male infant, the labour being rapid and uneventful.

The case is instructive on account of the well-marked aphasia and the fact that labour and the fœtus were quite unaffected by the drug. The aphasia is difficult to account for. Unless one assumes some specific action by bromide of potassium upon the cells or blood-supply of the vocal word centre one can only suppose it to be due to the general depression of the subcortical cells comparable to the temporary aphasia produced by exhaustion and debility.

Wanstead Park, Essex.

A CASE OF "ŒDEMA" LIMITED TO THE ARMS, FACE, AND NECK. ? CAUSE.

By J. M. BENNION, M.A., M.D., B.C. CANTAB., M.R.C.S. ENG.

THE patient, a married man, aged 40 years, was a painter by trade. His family history and his health previously to the present illness were satisfactory. On Nov. 4th, 1907, he came to my surgery complaining of pains in both thighs and forearms, which apparently were in the muscles. I gave him a mixture containing 15 grains each of sodium salicylate and potassium bicarbonate three times a day. One week later he consulted me about his arms being "swollen." On inspection both forearms were noted full and rounded. The skin was neither reddened nor hot. There was marked pitting on pressure on the dorsal aspects. The œdema was located to the posterior surface and the upper half of each forearm. On the backs of either hand were a few chilblains but no open wounds. The legs, feet, and the rest of the body were free from œdema. The patient was advised to give up work temporarily. The arms were massaged and he was ordered a mixture containing five minims each of nux vomica and Fowler's solution. By Nov. 20th the œdema of the left forearm had disappeared and that of the right was less marked. On the 22nd some swelling of the lids of the left eye was noticed. The lids of both eyes were very œdematous on the 24th. A few red blotches on the cheeks were also observed. The temperature and pulse were normal and remained so throughout the illness.

On Nov. 25th I asked my partner, Mr. T. W. Bailey, to see the patient with me. He was unable to find a cause for the man's condition and suggested his taking a mixture of iodide and mercury. On the 26th the œdema of the eyelids was less but it had spread over both cheeks. The patient complained of tenderness on pressure over both sterno-mastoid muscles and down the back of the neck. The voice was a little husky. He was put on a mixture containing 15 minims of liquor hydrargyri perchloridi and three grains of potassium iodide thrice daily. On the 27th the œdema of the face was less evident. The skin over both mastoid bones and sterno-mastoid muscles was slightly red and pitted a little on pressure. Œdema of the left forearm had reappeared. On the 28th the neck was more swollen and the voice was almost gone. The uvula and faucial pillars were injected and swollen. Both forearms were œdematous.

By Dec. 1st the patient, who had been in bed during the previous week, was better. The œdema of the eyelids, face, and neck had cleared up. The voice was less hoarse. The doses of mercury and iodide were increased to 30 minims and five grains respectively. On the 4th the patient felt quite well. The voice had quite returned. There was still slight œdema of both forearms. He was allowed out of doors on the 10th and no sign of œdema of either forearm was present after the 13th. The patient resumed his work early in January and has kept quite well up to the present time (April 18th).

The appearance of œdema in a patient is usually an important physical sign giving a clue to the nature of the disease. In the case described a careful examination of the man revealed no cause for his condition. The heart was sound and the urine was free from albumin. No evidence of thrombosis of any veins of the arms or elsewhere could be found. Angio-neurotic œdema[1] was considered as a possible explanation. But the history and clinical features of the

HUNTERIAN SOCIETY.

Discussion upon Rheumatism.

A MEETING of this society was held on April 8th, Mr. F. ROWLAND HUMPHREYS, the President, being in the chair.

Dr. FREDERICK TAYLOR opened a discussion on Rheumatism. With regard to its pathology he was convinced that it was an infectious disorder, and almost certainly microbic. The profession rightly demanded rigid proof of the specificity of an organism. With regard to diseases having a relationship to rheumatism, but once thought to be distinct, the first was chorea. Chorea was obviously toxic rather than a purely nervous disease. That it belonged to the infectious group was shown by the occasional occurrence of endocarditis in cases in which there had been no previous rheumatism, by the great frequency of endocarditis in fatal cases, and by the resemblance in the manner of death between some fatal cases of chorea and other nervous diseases such as hydrophobia and tetanus. Those three diseases were alike in being almost solely infectious disorders of the central nervous system and different in the area chiefly affected. The association of tonsillitis and various erythemata with rheumatism was recognised long ago. There were many forms of infective arthritis other than acute rheumatism, and it was reasonable to suppose that such affections in association with erythema and urticaria were due to some other condition, possibly some other toxæmia, than that of acute rheumatism. Wright thought that hæmorrhagic, erythematous, and urticarial lesions were often due to deficiency of calcium salts in the blood. He (Dr. Taylor) did not adopt the idea that an erythema was necessarily a manifestation of rheumatism. Again, it was difficult to look upon tonsillitis as necessarily due to rheumatism. The tonsils were specially vulnerable to causative microbes. The researches of the skilled bacteriologist were specially needed in regard to the relationship between acute rheumatism and chronic rheumatism or osteo-arthritis. Osteo-arthritis in the middle-aged and the old was very widespread and occurred in many thousands who had never had acute rheumatism. Hyperpyrexia was a complication of rheumatism which was a profoundly interesting mystery. From 1873 to 1877 there was an epidemic of hyperpyrexial cases in the British Isles which he did not think had been repeated. A committee of the Clinical Society reported on a number of such cases but without reaching any definite conclusion. It might be said that salicylic acid would guard against a recurrence of such epidemics, but the salicylate treatment was introduced, though perhaps not fully pushed, during the years when hyperpyrexia was rife. During 18 years (1888 to 1905) the admission of cases of acute rheumatism to Guy's Hospital numbered 1887, yet there were only seven cases of hyperpyrexia, two of which proved fatal. With regard to the salicylates, he considered 20 grains every four hours to be the best dosage. The question remained how to prevent carditis; and he would be glad if any subsequent speakers could say whether that had been any less frequent during the last 40 years. His impression was that rheumatic heart disease was as prevalent now as ever. Much had been said about the control of carditis, but he dissented from most of it, and when the heart was primarily affected carditis could not be obviated. He asked what view ought to be taken of rheumatism in regard to insurance practice. What view ought to be taken with regard to a proposer who had had within a few years a sharp attack of acute rheumatism, when the heart on examination appeared quite sound? 15 or 20 years might intervene between an attack of rheumatism and the onset of cardiac disease.

Dr. F. J. POYNTON said that to him rheumatism was a specific disease. It was not strictly a fever, as there might be no fever. He and Dr. Paine had investigated 40 cases in ten years and had isolated the diplococcus of the disease from many parts of the body. They were the first to reproduce experimentally and repeatedly rheumatic pericarditis and endocarditis. The conclusions which he and Dr. Paine had arrived at were that the micrococcus could be isolated in pure culture from the cardinal lesions of rheumatism, could by injections into animals cause similar lesions, and could be again isolated from these lesions in pure culture. He exhibited a number of specimens showing the artificially induced lesions in animals.

Dr. T. J. HORDER said that his attitude was that of a sceptic rather than that of an opponent of Dr. Poynton's views. Such of the specimens of the diplococcus rheumaticus as Dr. F. W. Andrewes and he had been able to investigate had given reactions identical with those of the fæcal streptococci obtained from cases of malignant endocarditis. He believed that the causal factor of rheumatic fever was as yet undiscovered, and that such bacteria as had been obtained had been connected with secondary invasions in a body invaded by the rheumatic virus.

Dr. A. P. LUFF dealt with the irregular manifestations of rheumatism. For every case of acute rheumatism the general practitioner perhaps saw a hundred of chronic rheumatism. The latter was really an affection of the white fibrous tissue, which had led Sir William Gowers to coin the word "fibrositis." The word "rheumatic" in that connexion was unfortunate. The condition was frequently started by cold and wet and it might be started by strain, as in the case of tennis elbow, golfer's elbow, &c. In the treatment the salicylates were useless except as relievers of pain. For the pain he knew nothing better than a combination of aspirin and pyramidon. For the fibrositis he knew nothing to equal iodide of potassium and he gave it in the largest possible doses. The local fibrositis might be relieved by the application of heat or by ionic medication. In his experience there was no necessity to diet patients suffering from fibrositis; there was no reason for the belief that it was associated with gout. He urged that the profession should finally abandon the uric acid fetich, uric acid being a harmless by-product.

Dr. F. J. SMITH asked for a definition of malignant endocarditis. The difference between it and ordinary endocarditis was only one of degree and he was in the habit of teaching that every endocarditis was ulcerative. The term endocarditis should be used with the addition of an adjective to denote the kind of microbe causing it when that was known.

Dr. O. F. F. GRÜNBAUM asked Dr. Poynton in what percentage of cases his cultures were obtained during life and ten days or more before death. That was very important, as a terminal invasion occurred in so many diseases. More evidence was wanted that the organism of Poynton and Paine was different from that of Andrewes and Horder.

Dr. SEYMOUR TAYLOR said that not infrequently one or other parent of the choreic child was rheumatic and the disease was preceded by or complicated rheumatism in many cases. In severe cases of chorea there was frequently a rise of temperature. In 30 per cent. of the cases the child had endocarditis or pericarditis. Moreover, chorea yielded to treatment by salicylates as quickly as to arsenic or other so-called remedies. He had had a child in hospital without a history of rheumatic fever who suffered from chorea. Lumbar puncture was done and Poynton's micro-organism discovered. That patient was quickly cured by salicylate of sodium.

Dr. POYNTON, in reply, said that the question of a terminal infection in his cases could be disposed of. Some of the patients from whom the micrococcus was obtained lived for years afterwards.

The discussion was adjourned.

UNITED SERVICES MEDICAL SOCIETY.

Probable Diseases of a Territorial Army.

A MEETING of this society was held on April 9th at the Royal Army Medical College, Millbank, London, S.W., Inspector-General Sir HERBERT MACKAY ELLIS, K.C.B., K.H.P., being in the chair.

Captain W. SALISBURY-SHARPE, R.A.M.C. (Vol.), read a paper entitled "The Diseases likely to Occur on the Occasion of the Mobilisation of a Territorial Army." He divided such diseases as regards causation into those due to a common cause and those directly communicable from man to man, and as regards treatment into the specific infectious fevers and the group of alvine disorders, including enteric fever. He pointed out that in the first line it would not be possible to make use of buildings for hospital purposes owing to the absence in many cases of such buildings as might be suitable for the purpose. The water-supply, again, would have to be taken from shallow wells or open streams, both of which needed careful protection on account of their liability to fæcal pollution. He next passed to the question of the disposal of excreta and pointed out that the great object to be aimed at was the elimination of all causes tending to favour the breeding of flies, which were far more fruitful causes of food contamination than was air-borne dust; he

It was found that the creatinin excretion maintained practically a level line and was probably not increased by the involution of the uterus, a result which was in harmony with the recent work on creatinin excretion. By applying the conception of autolysis to the process of involution of the uterus it was thought that a clearer idea of that process might be obtained. A very brief *résumé* of the main facts concerning autolysis was given, stress being laid on the fact that it was most rapid in an acid medium and in a bloodless organ. Dr. Longridge had observed that the wall of an autolysing uterus was acid in reaction and considered that the rapidity of the first stage of involution was due to this fact and to the fact that the uterus is anæmic during the first four or five days after delivery in a normal case. This anæmia is due to two factors, the retraction of the uterus and the effect of the kinking of the uterine arteries in reducing the blood pressure in them after delivery. Dr. Longridge thought that the conception of autolysis would help to explain many obscure points of uterine pathology, such as super-involution of the uterus and the changes in fibroid tumours, and would lead to considerable clarification of their ideas in regard to the relation of the liver to the toxæmia of pregnancy.

Dr. HERBERT WILLIAMSON and Dr. EARDLEY L. HOLLAND communicated a paper on a case of Intra-uterine Death of the Fœtus occurring in five consecutive pregnancies. The case was recorded of a patient, aged 24 years, who had given birth to two stillborn children at the twenty-sixth and twenty-eighth weeks of gestation respectively. Careful examination of the patient and her husband failed to reveal any signs of syphilis and no history of infection could be obtained. During the course of the next two years she gave birth to two more children, stillborn, at the eighth month. In her fifth pregnancy the child was found to be alive in the thirtieth week, and the induction of premature labour was recommended. Three weeks later she was spontaneously delivered of a stillborn child in Queen Charlotte's Hospital. Sections of the fœtal organs stained by Levaditi's method revealed the presence of the spirochæta pallida. She became pregnant again before the menses reappeared and throughout this pregnancy was treated with small doses of mercury and iodide of potassium. When examined on Oct. 17th the uterus reached to the costal margin and the fœtal heart could be heard. It was believed that nine lunar months' gestation had been completed and it was thought advisable to run no further risk but to induce labour. Labour was induced on Nov. 2nd and she was delivered of living twins, a boy and a girl. Both children were obviously premature and the amniotic sac of the female child contained an excess of liquor amnii. The children survived only a few days and post mortem neither showed syphilitic lesions, nor could spirochætæ be discovered in sections of the organs. Dr. Williamson and Dr. Holland brought forward the case as a contribution towards the pathology of intra-uterine death and stated their opinion that Levaditi's method of demonstrating the spirochæta pallida has given a new means of diagnosis and new indications for ante-natal treatment.

MEDICAL SOCIETY OF LONDON.

Malta Fever.

A MEETING of this society was held on April 27th, Dr. J. KINGSTON FOWLER, the President, being in the chair.

Colonel D. BRUCE, R.A.M.C., read a paper on Malta Fever. He said that in 1904 as the incidence of Malta fever among the garrison of Malta had increased to a marked extent the Royal Society, at the request of the Admiralty, War Office, and Colonial Office, sent out a Commission to Malta to investigate the disease. From the results of the experiments made by the Commission it seemed most probable that the micrococcus Melitensis (Bruce), the cause of the fever, gained an entrance to the body by way of the alimentary canal, and therefore by some infected food or drink. That led to an examination of foodstuffs, and among these the milk of the goat was one of the most important. Then followed the remarkable discovery that the goats in Malta acted as the reservoir of the virus of the fever. The goat was very much in evidence in Malta and supplied practically all the milk used. It must be confessed that the Commission had little hope that an examination of these animals would yield anything. Several goats had been inoculated and fed with the micrococcus and the result watched. There was no rise of temperature, no sign of ill-health in any way, but in a week or two the blood was found to be capable of agglutinating the specific micro-organism. Even then the goat seemed such an unlikely subject for Malta fever that the observation was in danger of lapsing. Nothing more was done for several months when by accident the matter came up again and it was decided to repeat the inoculation experiments. A small herd was procured for the purpose and, as an ordinary precautionary measure, their blood was examined before inoculation. Much to the surprise of the Commission several of them were found to react naturally to the agglutination test and that led to the examination and the discovery of the micrococcus Melitensis in the blood, urine, and milk. Some thousands of goats in Malta were then examined and the epoch-marking discovery was made that 50 per cent. of the goats in Malta responded to the agglutination test and that actually 10 per cent. of them were excreting the micrococci in their milk. Monkeys fed on milk from an affected goat, even for one day, almost invariably took the disease. At that time, curiously enough, an important experiment on the drinking of goats' milk by man took place accidentally. That was the case of the s.s. *Joshua Nicholson*. In 1905 this ship shipped 65 goats at Malta for export to America. The milk was drunk in large quantities by the captain and the crew, with the result that practically everyone who drank the milk was struck down by Malta fever. 60 of the goats (five having died) on arrival in America were examined and 32 were found to give the agglutination reaction, while the micrococcus Melitensis itself was isolated from the milk of several of them. Preventive measures were first begun in Malta in June, 1906. Of course, much opposition and prejudice were met with at first, but by dint of argument and explanation most of the regiments and military and naval hospitals agreed to banish goats' milk from their dietary. The result was very striking, for in 1907 there were only seven cases of Malta fever in the soldiers of the garrison and none at all among the sailors. It was evident, then, that the rational mode of preventing Malta fever was to keep people from drinking infected goats' milk. It was almost certain that practically all cases of Malta fever were caused in that way. The cases which had arisen in laboratories by accidental inoculation showed that other methods of infection were possible, but the fact that practically Malta fever ceased in the garrison on goats' milk being banished from the dietary was sufficient proof that all other modes of infection might be ignored. The seven cases of Malta fever among the garrison which occurred in 1907 were almost all traced to the drinking of goats' milk. It would be thought that as soon as the discovery was made known to the Maltese they would at once have set about purifying their herds of this infection. But this was not so. So far as Colonel Bruce was aware, up to the present time not a single infected goat had been slaughtered or anything done to remedy the outrageous state of affairs. At the present moment the Maltese goatherd was leading about his diseased animals and selling to his unwary clients an emulsion of micrococcus Melitensis as pure milk! It was a pity that in a long chronic disease, such as Malta fever, which seemed interminable alike to medical man and patient, there was no drug which would help to cut it short. But up to the present no specific drug had been discovered. They were driven, then, to treat the symptoms as they appeared. Some work had also been done in the treatment of this fever by anti-sera, but with no success. Malta fever had also been treated of late years by the injection of dead micrococci. It was constantly stated in the medical journals that that had given good results, and Malta fever was quoted as an instance of a disease which was successfully treated by that method. Reid and Bassett-Smith of the Royal Navy had published results but he (Colonel Bruce) must confess after reading their papers that he failed to see any proof whatever of that disease being modified for the better by these injections, even when controlled by the opsonic index. —After a brief discussion of the paper by the PRESIDENT, Dr. J. V. BELL, and Dr. E. D. MACNAMARA, Colonel BRUCE replied.

The PRESIDENT then announced that the Fothergillian gold medal for the best essay on some branch of practical medicine or practical surgery proposed by the trustees of the Medical Society of London or for a literary work on some branch of practical medicine or surgery had been awarded to Sir Almroth E. Wright.

infection was fallacious, because the uterus was so intimately bound up with its connective tissue and lymphatics that the removal of the infection by removing the uterus seemed hopeless. If a patient got into a chronic condition of pyæmia he could imagine that by removing the source of the infection in the uterus they might do a certain amount of good, as the extension of infection during the operation might be successfully overcome by the resistance set up by a long period of vaccination, so to speak. But in the early stage it did not seem possible to remove the uterus with its load of infection and open up the peritoneal cavity without giving the patient such a dose of the organism as would do away with any good got by removing the prime source of the infection.—Dr. O'Farrell said that Professor Frederic E. Sondern of New York, writing in the *New York Medical Journal* of June 16th, 1906, claimed that by means of a general and differential leucocyte count he was able not only to ascertain the presence of a septic infection but also to estimate the body resistance. Relative increase in polymorphonuclears indicated the presence of sepsis and the degree of leucocytosis indicated the condition of the body resistance. Professor Sondern considered it so important that he had an assistant on duty in his laboratory day and night so as to be able to examine any patient's blood and let the surgeon know without delay whether the blood conditions were such as to make operation desirable.—Sir W. J. Smyly said it was unlikely that any one of them would meet with more than a very few cases in which operative interference was required and as it had been laid down that they could not judge the value of any particular line of treatment upon less than 100 cases it would probably take some centuries before any one institution would yield a sufficient number of cases. It was evident that the great majority of cases spoken of by Sir A. Macan were localised, not general, sepsis. In douching the uterus they were liable to do harm by opening up channels for the absorption of septic materials. One of the first things they had to do in a case of acute fever following childbirth was to try to clear the uterus with the finger, and he did not think that there was any difficulty in doing so if they gave the patient an anæsthetic. He was not inclined to give up the flushing spoon-curette, and he thought that the introduction of the brush would be more dangerous than the spoon.—The President said that he divided puerperal infection into the mild, acute, and chronic types. The mild type was eminently suited for surgical interference. The chronic type was that dealt with for the most part by Sir A. Macan, and the acute type was outside the pale of all treatment. He divided operative treatment into the mild, the intermediate, and the drastic. Under the mild he put raising the bed, douches, exploration of the uterus, draining pus pools in the uterus, replacing a retroflexed uterus, and the removal of pieces of placenta and membrane by the fingers. These could be undertaken without chloroform in the patient's own bed and were highly successful. The intermediate (Pryor's) operation could be done in the patient's own bed but required an anæsthetic; it could be conducted without fear of injuring the patient, and it was largely diagnostic as well as curative. If they could get a pelvic peritonitis well established the patient would probably recover and no procedure was better for that purpose than plugging the whole pelvic cavity with iodoform gauze. He believed that it impeded the circulation in the lymphatics. Antistreptococcus serum was worthless when the disease had developed, though valuable as a prophylactic remedy. Where pus had burst into the abdomen he gave the serum straight off.—Sir Arthur Macan, in reply, said that it might require a hundred cases to make statistics but it did not require that number to enable them to have ideas on the subject. He had himself expressed his objection to the term puerperal fever but there was no other term that embraced all the states, including sepsis. The uterus had been recognised for a long time as the source of the infection, and theoretically they must recognise a point at which the removal of the septic centre would be sufficient to stop the spread of the disease. The earlier they operated the more successful they would be, but the more doubtful it would be as to the success of the operation.

Windsor and District Medical Society.—A meeting of this society was held on March 25th, Mr. W. A. U. Thomson (Maidenhead), the President, being in the chair.—Mr. William B. Holderness (Windsor) showed Preparations from a Carcinomatous Kidney removed by Mr. E. Hurry Fenwick in February. The patient, who was a man, aged 68 years, had now resumed his work.—The President showed a man, aged 33 years, with enormous Varicosities over the abdomen and thighs.—Mr. Joseph O. Skevington (Windsor) showed a young woman with well-marked Broad Lines Traversing the Skin in the region of the right shoulder and breast. They were thought to be degenerative but the nature of their causation could not be definitely determined.—Mr. A. E. J. Barker (London) read a paper on the Pre-operative Treatment of Non-malignant Disease of the Stomach. He said that surgeons were frequently asked to operate on patients with chronic gastric troubles which were not beyond the reach of other than operative measures. He then gave an outline of a typical case of this kind in which the patient suffered from chronic dyspepsia of some years' standing, with vomiting, wasting, epigastric pain and eructations, and described his own routine pre-operative course of treatment. This treatment, he said, always rendered an operation safer if it had to be performed, and might obviate the necessity for such interference if carried out thoroughly. The patient should be kept in bed. The food should be properly sterilised. The mouth and throat should be cleansed and any foul stumps of teeth should be extracted or stopped. The food most relied on by him was boiled bread and milk with salt, or beaten-up eggs, and carefully prepared broths. These should be given at regular intervals, and it was most important that they should be given in small quantities at a time, because the pylorus contracted under the stimulus of badly digested food and the material thus retained in the stomach was liable to decompose. A case illustrative of this was related in which repeated washing out of the stomach for several days caused a wonderful improvement in the condition of a much wasted man. He soon became cheerful and put on flesh, and no operation was necessary. Mr. Barker believed that it would be very advantageous to the patient if this procedure of lavage were adopted in the earlier stages of so-called dilated stomach.

Wigan Medical Society.—A clinical meeting of this society was held on March 12th, Mr. W. Berry being in the chair.—Dr. R. Prosser White read notes of several cases treated with a considerable measure of success by Vaccines and urged that in some cases where operation was hopeless or inadvisable this form of treatment should have a fair trial. He also exhibited the following cases: (1) Tuberculosis of the Hip with Sinuses, treated with T.R.; (2) Scirrhus of the Mamma, with a Staphylococcic Infection treated with Antistaphylococcic Vaccine and much improved; (3) Tubercle of the Testis, treated with Hetol; and (4) Folliculitis Decalvans treated with Antistaphylococcic Vaccine.—Dr. C. G. Edmonston showed the following cases: For Mr. Berry: (1) A case of Strangulated Hernia, where 38 inches of bowel were resected for gangrene; (2) Wiring of Fracture of the Lower Jaw (compound); (3) Thyroidectomy, local anæsthesia, solution of cocaine 1 per cent.; and (4) a case shown at a former meeting, with Abdominal Tumour, which had since disappeared.—For Mr. W. Mitchell Roocroft: (1) A Hæmatocele of the Lesser Sac treated by Operation; (2) Paralysis of the Muscles of the Right Shoulder due to strain; (3) case of Icterus, probably malignant; and (4) Epispadias.—For Mr. C. R. Graham: (1) Thiersch Graft; and (2) case of Biliary (?) Colic for Diagnosis.—Mr. C. M. Brady showed (1) a case of Excision of Half the Lower Jaw in a young girl for Sarcoma; and (2) a Meningocele in a very young Infant.—Dr. Harry Holmes showed a case of Cataract Extraction.—Dr. Blair showed a case of Multiple Serositis. ——A meeting was held on April 14th, Mr. Roocroft being in the chair.—Mr. W. Thelwall Thomas read a paper on Renal Calculi, Diagnosis and Treatment, based chiefly on the records of a series of 33 cases under his own care. Mr. Thomas emphasised the value of x rays in the confirmation of the diagnosis and suggested that if it were possible to obtain a really good skiagram a surgeon was barely justified nowadays in operating unless and until such a photograph had been obtained. He exhibited a large number of very beautiful x ray photographs taken by Dr. C. Thurstan Holland of Liverpool.—The paper was followed by a discussion.

also referred to various facts connected with the incidence of summer diarrhœa at times and in places where flies were more likely to be an active cause than dust. He quoted from the experience of Dr. H. H. Tooth and others in South Africa in support of his contention. In his opinion the best way to dispose of excreta, keeping the above object in view, was that advocated by the late Dr. G. Vivian Poore in his "Flies and the Science of Scavenging." That method was the burial of all excreta in shallow trenches before the eggs of flies could be laid in them. Half an acre should on this principle be sufficient for 1000 men for a year. The method had the advantage of being simple and requiring but little in the way of appliances. Stationary hospitals would as a rule be in the neighbourhood of, if not actually in, a town of some size. The water-supply would be that of the town, but it would be advisable to dispose of the refuse of these institutions by burial and not by connecting the hospital with the drainage of the town in question. Coming to the diseases actually to be expected on the occasion of mobilisation, he said that in his opinion those of the alvine class would be by far the most important, and he emphasised the importance of both constipation and diarrhœa being early recognised and treated, as being both of them likely to be precursors of more serious disorder. Dysentery and enteric fever were then touched on, together with a reference to the difficulty of distinguishing which amongst the enormous mass of alvine and febrile diseases were not enteric fever. The isolation of cases of enteric fever was insisted on. Diphtheria and measles were referred to and the danger of the latter when large numbers of men were congregated together was mentioned. Pneumonia and rheumatic fever were also touched on. In speaking of small-pox it was pointed out that no provision was made for the effective vaccination of the Territorial Army. The absence of systematic secondary vaccination in this country and the number of individuals who escaped even the primary operation were considered to constitute a grave danger. In conclusion Captain Salisbury-Sharpe said that he had worked on the assumption that some months would elapse between mobilisation and the actual outbreak of hostilities or invasion. His paper was not intended to refer to actual war conditions.

Colonel **DOUGLAS WARDROP**, R.A.M.C., said that he doubted if there would be so much enteric fever as Captain Salisbury-Sharpe anticipated; he thought that with carefully selected camps and men coming from healthy homes better results might be hoped for. Indian experience made him sceptical of the infallibility of an earth system of disposal such as advocated by Dr. Poore and supported by the lecturer, in the absence of a highly trained conservancy establishment.

Major W. S. **HARRISON**, R.A.M.C., said that it was a pity that no reference had been made to the necessity of educating the soldier in peace for the necessary exposure to infection that he must expect in war. He referred to the desirability of protective inoculation against enteric fever, pointing out that recent experiments showed that the enteric fever bacillus could live for 60 days in unsterilised earth, and that therefore in an earth system of disposal there would be a danger of establishing foci of infection.

Lieutenant-Colonel H. J. **FLETCHER**, R.A.M.C., referred briefly to the experience of the Americans during the early part of the Spanish war and expressed the opinion that principal medical officers of territorial divisions should take steps in advance of mobilisation to counteract enteric fever.

Major F. J. **WADE-BROWN**, R.A.M.C., and Lieutenant-Colonel C. H. **MELVILLE**, R.A.M.C., also took part in the discussion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

An Abnormal Placenta.—Operative Treatment of Puerperal Infection.

A MEETING of this section was held on April 10th, Mr. E. **HASTINGS TWEEDY**, the President, being in the chair.

Mr. J. **SPENCER SHEILL** read a pathological report by Dr. R. J. **ROWLETTE** on the Abnormal Placenta exhibited at the previous meeting of the section, as some of the Fellows then present had stated that they had never seen a specimen similar to the one exhibited by Mr. Sheill. The placenta was slightly larger than normal and quite firm. The umbilical vessels were very congested and stood out prominently on the surface of the placenta. Completely surrounding the attachment of the cord and at a distance of about two inches was a raised ridge, varying from one and a half to two and a half inches high; it bent towards the cord so as to form a deep fossa, the inner surface of the ridge being in apposition with the surface of the placenta. The membranes were closely adherent to the surface of the placenta, passing into the depth of the fossa and then over the ridge. Under the microscope the placental tissue was normal. At the ridge, however, the membrane was lifted from the tissue by a great mass of fibrinous coagulum which was quite firm. The greater part of the ridge seemed to be composed of fibrin. The condition was apparently due to a sub-membranous hæmorrhage.—Sir **ARTHUR V. MACAN** expressed the opinion that it was simply an exaggerated placenta circumvallata.—Mr. **SHEILL**, in reply, said that although he was unable to suggest a probable cause for this placental abnormality yet he could not agree with Sir Arthur Macan's opinion, inasmuch as he understood that the so-called placenta circumvallata invariably showed the chorion forming a rigid annular fold at the inner limit of the margin. Neither did he think that it was a case of placenta marginata, for in these the chorion usually left the placenta *before* reaching its margin, thereby leaving a border free of membrane. In his specimen the chorion was attached all round to the placental margin in the usual way.

Dr. A. N. **HOLMES** opened the adjourned discussion on Sir Arthur Macan's paper on the Operative Treatment of Puerperal Infection. He said that there was a difficulty in deciding with a case not undoubtedly septic as to whether an operation was justifiable or not. He had seen cases apparently at the point of death get perfectly well. Evacuation was, of course, the best means of dealing with localised pus; and the making of an opening through the posterior fornix—an easy operation which did not necessitate the removal of the patient from bed—had been followed by good results. When the number of septic cases that existed was considered the mortality was really very small, and it would be unwise to operate in all cases until differential diagnosis was more perfect.—Professor **ALFRED J. SMITH** said that they accepted generally the two great classes of infection—pyogenic and saprophytic; and they divided the former into the forms in which the infection was carried—namely, (1) by the lymph-ducts and (2) by the blood stream. Dr. Bumm had demonstrated the fact that if a patient was infected by the streptococcus it developed and spread with such rapidity that there was no time for the surgeon to intervene. They were all in agreement as to the necessity of draining in cases of pus formation, though there was a difference of opinion as to the way in which they should reach the abscess. Sir Arthur Macan had proposed a special operation with a view to prevent the occurrence of general peritonitis, but he (Professor Smith) could not understand the advantage of packing the entire pelvic cavity, seeing that the uterus, in a case of septicæmia after confinement, was almost up to the umbilicus, and that on the posterior wall of the uterus there was the great lymphatic plexus carrying large numbers of streptococci. On the Continent and in America cases had been successfully treated by ligation of the inflamed veins but the whole difficulty consisted in deciding when they should interfere by operation.—Dr. R. D. **PUREFOY** said that he refused to believe that any examination of the contents of the uterus would enable them to make up their minds in every case, or even in any considerable number of cases, on the point of operative interference. In the cases of streptococcus infection the spread of the disease was so rapid and its diffusion through the system so general that surgical measures did not hold out hope of saving life.—Dr. H. **JELLETT** said that the more he thought about the subject the more hopelessly he seemed to be at sea. He could not understand where the operative treatment of acute puerperal fever came in. The operative treatment of local infections had been recognised for some time, but this was not what they were concerned with. Even if the presence of streptococci in the uterus was shown the bacteriologist could give them no help as to the virulence of the organism until after injection into animals, and by that time either the patient was better or it was too late for operation. If the infection had not extended into the peritoneal cavity it was contrary to all present-day ideas to open up the cavity. If the infection had gone beyond the uterus the analogy of limb a few weeks' duration a skilled opinion should be taken, and he very rightly says that many lives would be saved and much suffering avoided if this rule were only more widely recognised and acted upon. In tuberculous laryngitis rest of the voice is strongly insisted upon and milder forms of treatment are given precedence over the radical measures recommended by some authors. In removing foreign bodies from the trachea the direct method of removing the body through a Killian's tube is recommended and if this fails recourse should be had to tracheotomy. The chapters on paralysis and various neuroses are very clear and explicit. In discussing laryngeal vertigo all the various views that have been expressed as regards its origin are discussed. At the end of the book the author gives a collection of 75 prescriptions for various remedies for local application and internal administration.

Mr. Tilley's book, which we gather is in a way intended as a successor to the volume which he edited with Dr. F. de Havilland Hall, has certainly achieved a marked superiority over its predecessor. It is clearly written, well illustrated, and readable, and is a book to which students and practitioners of medicine may turn with confidence.

The Diagnosis and Treatment of Diseases of Women. By HARRY STURGEON CROSSEN, M.D., Clinical Professor of Gynæcology, Washington University; Consulting Gynæcologist to Bethesda Hospital, St. Louis, &c. St. Louis: C. V. Mosby; Medical Book and Publishing Company. 1907. Royal 8vo, pp. 812, 700 illustrations. Price $6.

THE most striking feature of Dr. Crossen's text-book is the large number of illustrations which it contains. They have been selected from all the most important works on gynæcology and are supplemented by original drawings showing the various methods of carrying out the proper examination of the pelvic organs. There are also some most interesting and helpful figures to indicate the areas of pain in different pelvic affections and the anatomical relations of the various structures in the abdomen. An ingenious device is adopted to demonstrate the limits of tumours or collections of fluid in the abdominal cavity. Black webbing is gummed on the abdomen over the area which it is wished to outline and in this way its exact limits are very clearly defined in the drawings reproduced. The book is almost entirely concerned with the diagnosis and treatment of the diseases of women. No notice is taken of other considerations such as etiology or pathology except so far as is absolutely necessary for the sake of completeness, and but a small amount of space has been taken up with detailed descriptions of the technique of major operations.

The author's teaching on the majority of subjects is sound and trustworthy. The chief facts are put clearly and succinctly and medical treatment is considered in considerable detail. After two chapters devoted to general points in diagnosis and treatment, the affections of the various genital organs are discussed, an anatomical classification being adopted. The section dealing with the indications for, and the use of, pessaries is particularly good and clear, while the operative procedures suitable for the treatment of backward displacements of the uterus are given very fully. After a very careful summing up of all the evidence available for coming to a certain conclusion as to the real dangers of fibroid tumours the author concludes that as a general rule such tumours are best removed and that in quite a notable percentage of the cases symptoms requiring treatment arise sooner or later. As he rightly points out, the question is a difficult one to decide because no one observer is able to follow the natural course of these patients for a sufficient length of time, and fibroids which are noted when first seen as giving rise to no symptoms may well be the cause of very considerable disturbances of the patient's health in after years. The known facts at our disposal are not yet sufficient to enable us to state precisely what are the possible and probable dangers to a patient who has a fibroid tumour of the uterus; nor, indeed, at the present day, when it is becoming, rightly or wrongly, more and more the custom for gynæcologists to remove these tumours in the early stages of their growth, are we likely to obtain a sufficient number of long histories of these cases to enable us to come to a certain conclusion. That they are not infrequently a source of danger is certain and that the best results are likely to follow their removal when still small is beyond dispute, but what are the chances of an individual patient running any risk to her life from the presence of a simple uncomplicated fibroid is a problem which we cannot answer with certainty. Other interesting questions, as, for example, the treatment of cancer of the cervix by abdominal section and the operative treatment of pelvic inflammation, are discussed fully and the author's conclusions are marked by sound judgment and are such as will commend themselves to most English gynæcologists.

The book is a good specimen of its class and is likely to prove helpful to the student.

Practical Diagnosis: the Use of Symptoms and Physical Signs in the Diagnosis of Disease. By HOBART AMORY HARE, M.D., B.Sc., Professor of Therapeutics in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital. Sixth edition, revised and enlarged. Illustrated with 203 engravings and 16 plates. London: Henry Kimpton. 1907. Pp. 616. Price 21s.

WHEN a student commences the study of practical medicine his thoughts are generally so taken up with the technique of eliciting physical signs and the recognition of the many varieties of adventitious sounds which may be heard, for example, on examining the chest, that he is liable to forget the importance of being able to deduce the necessary conclusions from these signs. In other words, his attention is devoted to obtaining physical signs rather than to reading them. Further, he is prone to rush at a diagnosis, basing his opinion upon one physical sign and forgetting that a correct diagnosis can only be arrived at by a consideration of an assemblage of signs and progression of symptoms. In a short paragraph placed opposite to the title-page of the volume now before us Dr. Hare expresses a similar dictum and adds: "It is as futile for a physician to attempt to base a diagnosis upon one symptom as for an architect to attempt to determine the appearance of a house by seeing one of the stones which has been removed from its walls."

Dr. Hare's intention in writing this book was to place before the physician and the student the subject of medical diagnosis as it is met at the bedside. To accomplish this the symptoms used in diagnosis are first discussed and their application to determine the character of the disease follows. That the author has successfully accomplished the task which he set himself is proved by the fact that a sixth edition of the work has been called for.

For purposes of reference the book will be found of special value since it is written on a plan most easily followed in practice—namely, forming a diagnosis by grouping the symptoms. For instance, if vomiting is a marked symptom in the case which is being investigated, in the chapter under that heading will be found a description of the various causes of vomiting and its diagnostic significance, together with the differentiation of each disease in which this phenomenon is met with. By carefully studying this work the student will obtain considerable insight into the information which may be obtained from careful observation. For instance, the chapters dealing with the hands and arms and the feet and legs contain numerous hints

Reviews and Notices of Books.

A Manual of the Practice and Theory of Medicine. By Sir WILLIAM WHITLA, M.A., M.D. R.U.I., LL.D., Senior Physician to, and Lecturer on Clinical Medicine at, the Royal Victoria Hospital; Professor of Materia Medica and Therapeutics in Queen's College, Belfast. In two volumes. London: Henry Renshaw. 1908. Pp. (two volumes) 1900.

Sir William Whitla states in the preface to this book that the aim of the work is to afford to the busy practitioner, in the most convenient and condensed form, a series of independent articles upon the different diseases (including those of the skin) which fall under the province of the physician. After a perusal of the two volumes we agree with the author that a more correct and suitable title for the work would have been "A Dictionary of Medicine" or "A Medical Index." Sir William Whitla feared, however, that such a nomenclature would lead to confusion as regards his "Dictionary of Treatment," to which the books now before us may be accepted as an introduction. The dictionary form of the work has necessitated a certain amount of repetition, as the aim of each article is to give a condensed and more or less isolated description of the etiology, pathology, symptomatology, diagnosis, and a brief *résumé* of the treatment of each medical affection. That portion of each article which deals with the subject of differential diagnosis is planned so that as far as possible cross-references are avoided, the reader being enabled to contrast the more important distinguishing clinical features of diseases liable to be confused with each other without having to turn to different portions of the work.

Sir William Whitla has succeeded in placing a vast amount of information within these two volumes. The various sections are well written and comprise a full account of the numerous diseases which are considered. The paragraphs dealing with etiology and pathology are fully up to date, the clinical phenomena are well described, while numerous valuable hints are given in regard to treatment. We have been particularly interested in certain of the sections. For instance, the remarks on broncho-pneumonia are well worthy of careful study, for the etiology of this condition is not generally understood. The author points out that two forms of the disease may be recognised, the primary and the secondary, and the causal factors at work differ in each case. In the primary form the etiological factors may be accepted as those which are present in ordinary acute lobar or croupous pneumonia, with the exception that the disease is practically confined to childhood. In the secondary form, whilst the pneumococcus is sometimes present, there are almost invariably other micro-organisms acting as well, and we agree with the author when he says that the generally accepted view of the origin of this form of the disease is that of a multiple infection in which the pneumococcus need not necessarily figure. A good account is given of the morbid anatomy of broncho-pneumonia and its clinical aspects are carefully detailed.

The section dealing with Bright's disease, acute and chronic, will also be found instructive, especially those portions dealing with treatment. Speaking of chronic interstitial nephritis the author maintains that there are few incurable conditions which the physician can approach with the same calm confidence of being able to prolong life and to retard the natural progress of a disease which, though ultimately proceeding to a fatal issue, may be modified or for a time arrested by judicious management. Useful directions are given as to the general course to be adopted with patients suffering from this condition.

Dyspepsia, the result of gastric neurosis, is considered at length, special stress being laid on the chemical pathology and on treatment. Three types of gastric neuroses are described: (1) sensory; (2) secretory; and (3) neuro-motor. This classification is a convenient and practical one. The student is liable to neglect a study of this common malady whilst attending the wards and the out-patient rooms, but when entering on practice he will require to systematise his knowledge on the subject and the sections contained in this text-book will help him to do so.

Excellent accounts are given of tuberculosis as affecting the various organs of the body, especially the pulmonary variety. The sections on the specific fevers are full and explicit, the remarks on diagnosis being especially valuable. The section devoted to enteric fever is one of the best in the book and we may draw the reader's attention to the observations on prognosis which will be found of considerable aid in actual practice.

We can cordially recommend this book to the practitioner as a useful work of reference. Its contents are rendered more suitable for this purpose by the fact that each volume contains a complete index to the two volumes, so that any required information can be obtained easily.

Diseases of the Nose and Throat. By HERBERT TILLEY, B.S. Lond., F.R.C.S. Eng. With 126 illustrations. London: H. K. Lewis. 1908. Pp. 539. Price 14s. net.

Mr. Tilley first gives a brief account of the anatomy and physiology of the nose. The next chapter consists of an all too short description of the examination of the nose and the methods used; this portion of the work might with advantage be considerably enlarged. He next proceeds with a description of the various forms of rhinitis. We notice that when describing the after-treatment he does not warn the tyro in nasal surgery that after the use of the galvano-cautery the patient should be prohibited from blowing the nose for some hours in order to diminish the risk of hæmorrhage. In dealing with rhinitis sicca a little more space might have been occupied, especially as regards the views of continental authorities that the bleeding polypus of the septum is often found in connexion with this disease. In membranous rhinitis we observe that the author admits the possibility of other infections being present besides that of the diphtheria bacillus. The part of the book on nasal reflex neuroses leaves nothing to be desired, the whole treatment of the subject being extremely temperate, and Mr. Tilley is to be congratulated on the excellent way in which he discusses the matter. He divides nasal obstruction into two classes—one in which the structural changes are brought about by mechanical factors, and another in which the general symptoms are due to an unnatural method of breathing. The preparation known as eudrinine is recommended as being the best local anæsthetic for operations on the septum. With regard to the etiology of nasal polypi both Woakes's and Yonge's theories are given but the preference of probability is given to Woakes's. When the reader comes to diseases of the accessory sinuses of the nose he will appreciate the intimate knowledge which is exhibited and the careful manner in which all operative procedures are discussed and described. In the frontal sinus operation the incision recommended is through the eyebrow. This occasionally has the disadvantage of destroying the hair bulbs and leaving a very unsightly scar. The only complaint we might make of this section is that the description of Killian's operation is, perhaps, enough for the expert but the information given is certainly not sufficient for the novice.

The second half of the book is devoted to diseases of the larynx. The author's instructions as to the use of the laryngoscope are sufficiently full. He lays much stress on the golden rule that when an adult complains of hoarseness or alteration of the voice of more than nearly all of the complications and accidents which have occurred as a result of the injection of paraffin have followed the employment of a paraffin melting below 110° F., and we agree with the authors that the employment of a paraffin of a melting point higher than this is desirable. We cannot agree with Eckstein that 136° F. is a desirable melting point, for the risk of burning is great and the practical difficulties during use are by no means small. It must be recognised that the use of paraffin in surgery is reasonable and gives good results in careful hands, but its employment is not without a small element of danger and even fatal results have occurred. A skilful surgeon, however, can sometimes by the use of paraffin produce results unattainable otherwise and the risk is small. When a paraffin of suitable melting point is chosen the results are apparently permanent.

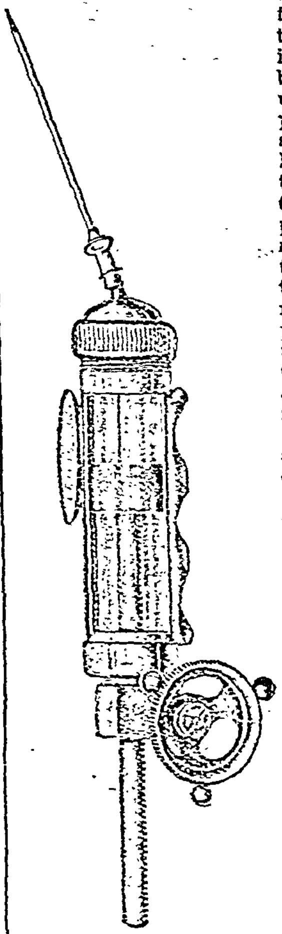
A Manual of Orthopædic Surgery. By AUGUSTUS THORNDIKE, M.D., Assistant in Orthopædics at the Harvard Medical School; Visiting Surgeon to the House of the Good Samaritan; Assistant Orthopædic Surgeon to the Children's Hospital, &c. With 191 illustrations. London: Rebman, Limited. 1907. Pp. 401. Price 10*s.* 6*d.* net.—There is room for a small book on orthopædic surgery. The subjects included under this title are indeed mentioned and described in the general text-books of surgery but the senior student finds that he requires more, and such a book as this is very well suited to supply this want. The descriptions of treatment are sufficiently lengthy to be of practical use and treatment is after all the part that is most needed. The author is moderate in his views and there is hardly any statement to which exception need be taken. The book is adequately illustrated. We do not know a better work on orthopædics for its size.

New Inventions.

NOTE ON A NEW SYRINGE FOR THE INJECTION OF IODIPIN, WITH A DESCRIPTION OF THE METHOD OF USING.

IODIPIN, an additive compound of iodine and sesame oil, is a thick yellow oil and is prepared in two strengths—namely, 10 per cent. and 25 per cent. The latter is that most commonly employed for subcutaneous or, preferably, intramuscular injection. Hitherto the intramuscular injection of iodipin has been always attended with a certain amount of difficulty—firstly, owing to the oily and viscid properties of the preparation, which, even when the syringe has been carefully warmed over a Bunsen flame, necessitates considerable force being employed in giving the injection; secondly, the comparatively long time required for the procedure (especially when large doses of iodipin are to be given, i.e., up to 30 cubic centimetres); and last, and by no means least, there is the danger of piercing a vein. The force required to push down the piston makes it almost impossible to hold the instrument absolutely still. The lateral quivering movement thereby produced is apt to cause unnecessary pain, and the up-and-down movement in the long axis of the needle may lead to penetration of a vein, thus leading to the introduction of iodipin into the venous circulation, and so producing a pulmonary embolism and its attendant dangerous consequences. There is also an unpleasant side to the operation—the prolonged period required to give the injection and the disagreeable and often painful sensation caused by such a large quantity of fluid penetrating the tissues of the buttock may give rise to the phenomena of vertigo or syncope. The psychological element has also to be taken into consideration and patients often become nervous and frightened and so are prevented from keeping absolutely still.

Now that iodipin for intramuscular injection is being more widely employed it may be of advantage to introduce a syringe by the use of which these disadvantages can be overcome. This syringe was invented by Dr. Anton Lieven of Aix-la-Chapelle, and after considerable experience in its use I have come to the conclusion that it is quite the best. The salient points of the syringe are: 1. The piston is moved up and down by a rack-and-pinion movement, actuated by a small wheel, with a milled edge, at the side. By this means a quick emptying of the syringe is made possible and considerable force is attained which can be regulated at will. The simple turning of the wheel does not produce any kind of movement or "kick" of the needle, so that all danger of unintentional movement of the needle point is eliminated. 2. The nozzle, on to which the needle fits, is bent at an obtuse angle, so that the holding of the syringe is facilitated if the injection is being given to the patient in an upright position. 3. In order to prevent any rotation of the syringe and also to give a good hold to the fingers when giving the "stab" which is to introduce the needle there are "rests" provided on each side of the metal casing, on the one side for the thumb and on the other for the three fingers. The injection may be given either with the patient lying on a couch or in the upright position. The skin of the buttock is cleaned with ether and then rubbed over with a swab moistened with a solution of biniodide of mercury. The actual situation for the introduction of the needle is preferably in the outer and upper quadrant of the buttock, there being said to be fewer vessels in this locality. The needle, having been previously sterilised by boiling in a solution of common soda, is attached to the nozzle of the syringe and is then introduced into the buttock by a sharp stab. The syringe is then removed, the needle being left *in situ*, and a short space of time is allowed to elapse in order that it may be seen if a blood-vessel has been entered, which mishap would at once become apparent by the exudation of a few drops of blood from the end of the needle. Should this occur the needle must be withdrawn and introduced afresh, and so on, until a spot is reached where no blood passes back through the needle. In the majority of cases there is no need to introduce the needle a second time. The syringe, having been warmed over a flame, is now fitted on to the needle and emptied by rotating the wheel. The rate at which the syringe should be emptied should be gauged by the amount of pain and discomfort caused to the patient. The syringe and needle are then withdrawn, the site of the injection is massaged for a few seconds with the finger tips, and a dressing of gauze and collodion is applied.



The maker of the syringe is Mr. A. Bildheuser, Kleinkölnstrasse, Aachen.

M.R.C.S. Eng., L.R.C.P. Lond.,
Assistant in the Skin Department, St. George's Hospital.
Harley-street, W.

INVALID CHILDREN'S AID ASSOCIATION.—The annual meeting of the Invalid Children's Aid Association will be held, by kind permission of the Duke of Westminster, at Grosvenor House, Upper Grosvenor-street, W., on Wednesday, May 13th, at 3 o'clock. Sir Edgar Speyer will preside and the Reverend Father Waggett, Dr. Andrew Lang, Mr. D'Arcy Power, F R C.S. Eng., Mr. E. A. H. Jay, L.C.C., and Mrs. Bourchier (Violet Vanbrugh) will be among the speakers. Admission will be by tickets only, application for which may be made to the secretary, 69, Denison House, Vauxhall Bridge-road, Westminster, S.W.

which will prove of great aid in diagnosis. The many deformities of the limbs are admirably described and a careful consideration is afforded of the differential diagnosis of the various alterations in the appearance of the hands and feet produced by diseases of the nervous system.

When engaged as "clinical clerks," either in the wards or out-patient rooms, students will find this work of great value to them. For although clinical work can only be studied by the actual examination of patients, nevertheless a guide of the nature of Dr. Hare's manual is certainly desirable. The book is well printed and the numerous illustrations are beautifully executed.

The Black Death of 1348 and 1349. By FRANCIS AIDAN GASQUET, D.D. London: George Bell and Sons. 1908. Pp. xxv.-272. Price 6*s.* net.

Dr. Gasquet, who is the Abbot President of the English Benedictines, is well known as one of the most learned members of the great religious order which since the time of its foundation has given itself with special devotion to learning. The book now before us is a reprint of the first edition, which appeared in 1893, with one or two additions and corrections. The Great Pestilence, for the name "Black Death" was comparatively modern,[1] as Dr. Gasquet points out on p. 7, ravaged the whole of Europe during the period 1348-50. It was apparently a particularly malignant form of Oriental plague mainly of the pneumonic type. One unusual feature about the epidemic was the way in which animals were affected. Not only rats, but dogs, cats, and sheep suffered greatly. Pigs and cattle are also mentioned in contemporary records as being attacked with fatal results. The mortality amongst human beings was appalling; for instance, in England and Wales about half the whole population died. Such a cataclysm is of interest not merely from the medical point of view but even more from that of the historian and the student of social events. For, to quote Dr. Gasquet, the Great Pestilence "formed the real close of the Mediæval period and the beginning of our Modern age; ...... to use a modern expression, labour began then to understand its value and assert its power." In fact, all seemingly settled institutions were broken up and had to be built up anew.

Dr. Gasquet's book deserves careful study by all medical men and by all who are concerned with the health of the body politic. Its style is lucid and simple and we may add without fear of being misunderstood that the chief value of the book is that the statements are not those of Dr. Gasquet but of contemporary writers who wrote with first-hand knowledge. But the arrangement of these statements, their codifying, and the conclusions to be drawn from them are Dr. Gasquet's, which is as much as to say they are those of a learned, impartial, and judicious critic.

LIBRARY TABLE.

A Course of Practical Organic Chemistry. By T. SLATER PRICE, D.Sc., Ph.D., F.I.C., Head of the Chemical Department of the Birmingham Municipal Technical School; and DOUGLAS F. TWISS, M.Sc., A.I.C., Lecturer on Chemistry at the Birmingham Municipal Technical School. London: Longmans, Green, and Co. 1907. Pp. 239. Price 3*s.* 6*d.*—This book provides a most useful practical course in organic chemistry and is modelled on the lines of the *Board of Education* syllabus which is sufficiently comprehensive to have necessitated hitherto the consultation of different books for different parts of the subject. The syllabus is divided into three stages corresponding with Parts I., II., and III. of this book. The opening chapter deals with elementary proceedings, such as the determination of physical constants and the detection of the elements and gives a few preliminary notes on preparations. Methane, ethyl alcohol, formic acid, acetic acid, formaldehyde, ether, ethyl compounds, and acetone follow, to be succeeded by chapters on the acids, urea, cyanides, starches, sugars, and so forth, this part concluding with a scheme for the identification of any compound contained in the first stage of the syllabus. More advanced work follows in Parts II. and III. The paragraphs on preparations are excellent and eminently practical, and the tests described bear the evidence of a laboratory acquaintance with their value. The scheme is worked out thoroughly and clearly from beginning to end and should make what is to many often a difficult course easy and intelligible.

Annales Médicales et Bulletin de Statistique de l'Hôpital d'Enfants Hamidié. VIII^me^ année. Edited by Dr. IBRAHIM PACHA, Director-in-Chief, in collaboration with the medical staff of the hospital. Constantinople: Imprimerie Osmanié: 1907.—This publication has now reached dimensions which any hospital might be proud to claim for its "reports" and is of great interest as showing to what extent the Western ideals of medical practice and research are becoming implanted in Eastern minds. Another pleasing feature of the *Bulletin* is the proof which it affords of the humanitarian interest taken by the Sultan of Turkey in the welfare of the sick and poor of his country. The Hamidié Hospital, which he founded in 1898 in memory of his daughter, the Princess Imperial Hadidjé, already owes much to his generosity, and this *Bulletin* chronicles the completion of a gynæcological wing at the expense of the privy purse and also the erection of a sanatorium for pulmonary tuberculosis in connexion with the hospital in the pine forest above the plain of Kutahia. The *Bulletin* states that the equipment of the hospital is now thoroughly in accord with Western requirements and one of its latest acquisitions is an installation of lighting and gas. Most of the papers are written in Turkish; they include clinical observations, scientific studies, and a little popular instruction in hygiene. Some few of them are communicated in French and German, amongst which are A Case of Strangulated Diaphragmatic Hernia, by S. E. Dr. Alexandre Pacha Kambouroglou; the Surgical Treatment of Hydatid Cysts of the Liver, by Dr. Léon de Lacombe; Erythema Infectiosum, by Professor Theodor Escherich; a Study of Recklinghausen's Disease, by Dr. Chukri Mehmed; and Vesical Calculus, by Dr. Raïf bey. The reports are well illustrated with reproductions of many photographs. A long list of honours which have been awarded to members of the hospital staff is printed in the annals.

Paraffin in Surgery: A Critical and Clinical Study. By WILLIAM H. LUCKETT, B.S., M.D., Attending Surgeon, Harlem Hospital; Surgeon, Mount Sinai Hospital Dispensary; and FRANK I. HORN, M.D., Assistant Surgeon, Mount Sinai Hospital Dispensary, New York City. With 38 illustrations. New York: Surgery Publishing Company. 1907. Pp. 116. Price $2.—The time had certainly arrived for the appearance of a work dealing thoroughly with the rôle of paraffin in surgery. Seven years have elapsed since Gersuny's original article appeared in the *Zeitschrift für Heilkunde* and much progress has been made. It must not be forgotten that the method was first introduced for the treatment of prolapse of the rectum, and the application of the method to the cosmetic relief of saddleback noses was a later development. In this little book the authors give a good account of the use of paraffin and they show what happens to the paraffin after it is injected. They prove fairly clearly that nearly all of the complications and accidents which have occurred as a result of the injection of paraffin have followed the employment of a paraffin melting below 110° F., and we agree with the authors that the employment of a paraffin of a melting point higher than this is desirable. We cannot agree with Eckstein that 136° F. is a desirable melting point, for the risk of burning is great and the practical difficulties during use are by no means small. It must be recognised that the use of paraffin in surgery is reasonable and gives good results in careful hands, but its employment is not without a small element of danger and even fatal results have occurred. A skilful surgeon, however, can sometimes by the use of paraffin produce results unattainable otherwise and the risk is small. When a paraffin of suitable melting point is chosen the results are apparently permanent.

---

[1] Dr. William Sykes, in an article, "On the Origin and History of some Disease Names," which appeared in our issue of April 11th, 1896, p. 1007, says: "The 'Black Death' which ravaged Europe during the years 1348-50 with such terrible results is not to be found in any contemporary literature under that name, which has been shown by Dr. Murray in the New English Dictionary to have had no more recondite a source than Mrs. Markham's 'History of England,' published no earlier than the beginning of the present century for the instruction of children."

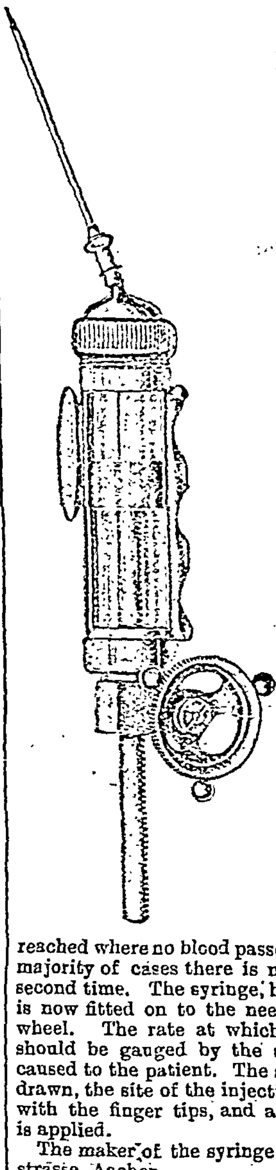
A Manual of Orthopædic Surgery. By AUGUSTUS THORNDIKE, M.D., Assistant in Orthopædics at the Harvard Medical School; Visiting Surgeon to the House of the Good Samaritan; Assistant Orthopædic Surgeon to the Children's Hospital, &c. With 191 illustrations. London: Rebman, Limited. 1907. Pp. 401. Price 10*s.* 6*d.* net.—There is room for a small book on orthopædic surgery. The subjects included under this title are indeed mentioned and described in the general text-books of surgery but the senior student finds that he requires more, and such a book as this is very well suited to supply this want. The descriptions of treatment are sufficiently lengthy to be of practical use and treatment is after all the part that is most needed. The author is moderate in his views and there is hardly any statement to which exception need be taken. The book is adequately illustrated. We do not know a better work on orthopædics for its size.

New Inventions.

NOTE ON A NEW SYRINGE FOR THE INJECTION OF IODIPIN, WITH A DESCRIPTION OF THE METHOD OF USING.

IODIPIN, an additive compound of iodine and sesame oil, is a thick yellow oil and is prepared in two strengths—namely, 10 per cent. and 25 per cent. The latter is that most commonly employed for subcutaneous or, preferably, intramuscular injection. Hitherto the intramuscular injection of iodipin has been always attended with a certain amount of difficulty—firstly, owing to the oily and viscid properties of the preparation, which, even when the syringe has been carefully warmed over a Bunsen flame, necessitates considerable force being employed in giving the injection; secondly, the comparatively long time required for the procedure (especially when large doses of iodipin are to be given, i.e., up to 30 cubic centimetres); and last, and by no means least, there is the danger of piercing a vein. The force required to push down the piston makes it almost impossible to hold the instrument absolutely still. The lateral quivering movement thereby produced is apt to cause unnecessary pain, and the up-and-down movement in the long axis of the needle may lead to penetration of a vein, thus leading to the introduction of iodipin into the venous circulation, and so producing a pulmonary embolism and its attendant dangerous consequences. There is also an unpleasant side to the operation—the prolonged period required to give the injection and the disagreeable and often painful sensation caused by such a large quantity of fluid penetrating the tissues of the buttock may give rise to the phenomena of vertigo or syncope. The psychological element has also to be taken into consideration and patients often become nervous and frightened and so are prevented from keeping absolutely still.

Now that iodipin for intramuscular injection is being more widely employed it may be of advantage to introduce a syringe by the use of which these disadvantages can be overcome. This syringe was invented by Dr. Anton Lieven of Aix-la-Chapelle, and after considerable experience in its use I have come to the conclusion that it is quite the best. The salient points of the syringe are: 1. The piston is moved up and down by a rack-and-pinion movement, actuated by a small wheel, with a milled edge, at the side. By this means a quick emptying of the syringe is made possible and considerable force is attained which can be regulated at will. The simple turning of the wheel does not produce any kind of movement or "kick" of the needle, so that all danger of unintentional movement of the needle point is eliminated. 2. The nozzle, on to which the needle fits, is bent at an obtuse angle, so that the holding of the syringe is facilitated if the injection is being given to the patient in an upright position. 3. In order to prevent any rotation of the syringe and also to give a good hold to the fingers when giving the "stab" which is to introduce the needle there are "rests" provided on each side of the metal casing, on the one side for the thumb and on the other for the three fingers. The injection may be given either with the patient lying on a couch or in the upright position. The skin of the buttock is cleaned with ether and then rubbed over with a swab moistened with a solution of biniodide of mercury. The actual situation for the introduction of the needle is preferably in the outer and upper quadrant of the buttock, there being said to be fewer vessels in this locality. The needle, having been previously sterilised by boiling in a solution of common soda, is attached to the nozzle of the syringe and is then introduced into the buttock by a sharp stab. The syringe is then removed, the needle being left *in situ*, and a short space of time is allowed to elapse in order that it may be seen if a blood-vessel has been entered, which mishap would at once become apparent by the exudation of a few drops of blood from the end of the needle. Should this occur the needle must be withdrawn and introduced afresh, and so on, until a spot is reached where no blood passes back through the needle. In the majority of cases there is no need to introduce the needle a second time. The syringe, having been warmed over a flame, is now fitted on to the needle and emptied by rotating the wheel. The rate at which the syringe should be emptied should be gauged by the amount of pain and discomfort caused to the patient. The syringe and needle are then withdrawn, the site of the injection is massaged for a few seconds with the finger tips, and a dressing of gauze and collodion is applied.



The maker of the syringe is Mr. A. Bildheuser, Kleinkölnstrasse, Aachen.

Trypanosomes and Trypanosomiases.

DR. NABARRO has done the medical profession in the United Kingdom a great service by the labour and industry which he has bestowed upon the translation of LAVERAN and MESNIL'S classical work on "Trypanosomes and Trypanosomiases."[1] He has produced an excellent translation and one free from the usual faults of language and style met with in so many translations. The drawback to the production of a translation of any work upon a subject of advancing knowledge is that before the book can be produced in its new and alien form fresh discoveries have rendered the original work well-nigh obsolete. Dr. NABARRO has overcome this difficulty and drawback by inserting in the text what has been done in elucidation of the subject of trypanosomes and trypanosomiases during the interval of time intervening between the issue of the original French edition and the appearance of the book in English. So skilfully have the interpolations been made that their inclusion in the text in no way interferes with the continuity of the narrative. Than Dr. NABARRO no one in this country is better qualified to deal with the subject matter of this important publication. A skilled bacteriologist, he has had the opportunity of studying trypanosomes and the ailments which they cause at close quarters in Uganda, where in 1903 he served as one of the members of the Royal Society Commission sent out from this country to study sleeping sickness.

The large volume before us constitutes an additional evidence of the marvellous advance in our knowledge of the etiology of disease consequent upon research in the field of tropical pathology. It is but seven years, on May 10th, 1901, to be precise, since FORDE found a parasite in the blood of a European on the Gambia which DUTTON subsequently recognised in December of the same year to be a trypanosome and appropriately named it the Trypanosoma Gambiense. FORDE and DUTTON'S observations were published in the *Journal of Tropical Medicine* of Sept. 1st, 1902, and since that time the literature not only of human trypanosomiasis but of trypanosomes in animals has multiplied with amazing rapidity. Our knowledge of trypanosomes and the diseases which they cause in animals has occupied attention for some 28 years. Although trypanosomes had been seen before 1880 in the blood of the trout (VALENTINE, 1841) and in the frog (GLUGE, MAYER, and GRUBY, 1842-1843) it was not until 1880 that the parasite was shown to possess a pathogenic significance by EVANS who demonstrated the trypanosome in the blood of horses and camels suffering from surra in India. The next great advance in the subject was made by BRUCE who in 1894 not only found trypanosomes to be the cause of nagana amongst horses and cattle in Zululand but subsequently proved the part played by tsetse flies in the distribution of the parasite. In South America an epizootic of horses termed "mal de caderas" was proved by ELMASSIAN and VOSGES in 1901 to be due to a trypanosome. In Europe dourine or "mal du coit" has been shown to be due to a trypanosome but is peculiar in that it is transmitted by coitus only. These were but the foundations on which the numerous observations now to hand were initiated, and in every laboratory in the civilised world experimental work has been actively carried on for the past decade, with the result that the literature of this subject has grown to an incredible extent. LAVERAN and MESNIL have undertaken the task of sifting, classifying, and reviewing this immense field of study and observation, and NABARRO has not only placed this storehouse of knowledge before English readers but has amplified the original work by important observations made by himself and others. Medical practitioners who are brought into contact with, or who wish to become acquainted with what is known concerning, sleeping sickness will naturally turn to the chapters in this volume dealing with human trypanosomiasis and the relation of trypanosomal infection to sleeping sickness. They will find that in April, 1903, CASTELLANI, working in Uganda, found trypanosomes in the cerebro-spinal fluid of patients suffering from sleeping sickness, an observation which was speedily confirmed by BRUCE and NABARRO. The trypanosome was shown by the last-named observers to be identical with the trypanosoma Gambiense and they also showed that the tsetse fly, glossina palpalis, is the principal transmitter of the disease. That other flies of this species, glossina fusca and glossina longipennis, are also capable of conveying the disease is certain, but so far the glossina palpalis is chiefly incriminated. The extent of NABARRO'S contributions to the volume, amounting in one section alone—namely, human trypanosomiasis—to about one-half of the entire text, greatly enhances the value of the work. Without these additions the translation would have been valueless as a representation of what is known at the present time concerning trypanosomes and the diseases which they occasion. By these additions, however, he original work is improved upon and students of the subject are provided with a complete, accurate, and recent account of the subject.

The treatment of trypanosomiases contained in Chapter XIII., extending to 24 pages, has been wholly written by NABARRO. The account of the part played by the lymphatic glands in the clinical history of sleeping sickness and the minute anatomy of the central nervous system and of other organs of the patients is also for the most part NABARRO'S writing. The lesions of the lymphatic glands in trypanosomal infection have been recently closely investigated. MOTT has shown that the deep paravertebral glands of the neck as well as other glands of the body in cases of sleeping sickness give in almost every instance signs of suppuration. To so marked an extent have lesions of the lymphatic glands been demonstrated that at the present time puncture of the cervical glands is regarded as the most trustworthy means of making the diagnosis of trypanosomiasis, and ZIEMANN and others state that to obtain a knowledge of the prevalence of trypanosomal infection in any given district it is only necessary to examine the cervical glands of the domestic animals indigenous to the district to come to a positive or negative conclusion in regard to the prevalence of the disease. In sleeping sickness areas also TODD and DUTTON found by practising gland palpation and puncture that every negro whose neck glands are enlarged without

[1] Trypanosomes and Trypanosomiases. By A. Laveran and F. Mesnil. Translated and much enlarged by David Nabarro, M.D., B.Sc. Lond. With coloured plate and 81 figures in the text. London: Baillière, Tindall, and Cox. 1907. Pp. 538. Price 21s. net.

THE LANCET.

LONDON: SATURDAY, MAY 2, 1908.

Dirty and Tuberculous Milk for London.

Although we are gradually making progress in the control of that great article of diet which we all consume in health and in disease, and which we give with such faith in its good qualities to the infants who are still born to us, we much doubt if the general public has any appreciation of the conditions in which a good deal of the milk that it consumes is drawn. Most medical officers of health are familiar with these conditions and are found lamenting them in their annual reports, but we question whether all medical officers of health, more particularly the part-time officers, have the knowledge of dairy farming to enable them to advise as to the proper precautions which should be taken. It is not improbable that at the present time the greatest stimulus to a better state of affairs is being exercised by the larger milk companies which, knowing the risks that they now incur by the supply of a specifically infected milk, are taking care by means of their contracts with the milk farmer and by the agency of inspectors in their own employ to protect themselves against the cruder forms of pollution. Evidence of this influence may be detected in rural districts around London, where for the most part the district councils have the meanest conception of their duties and where any official reform which takes place is due entirely to the efforts of the local medical officers of health and sanitary inspectors. For some years past Dr. William Collingridge has had samples of milk collected on arrival at Liverpool-street Station from the counties of Essex, Suffolk, and Norfolk—from, that is to say, the district which is more particularly known as East Anglia. These samples have been examined by Dr. E. Klein with reference both to their cleanliness and to their tubercle-conveying power, this latter attribute being ascertained by injection of the milk into guinea-pigs. The total number of the samples examined during 1907, 24, is small and therefore the percentages have but a limited value. With this reservation there is but small comfort to be derived from the fact that 54·2 per cent. were fairly clean, 8·3 per cent. tuberculous, and 37·5 per cent. dirty and unsatisfactory. It has, too, to be added that these results seem to agree generally with those obtained during the previous three years, and more particularly is this true of the tuberculous milk, the percentages for which varied from 7·7 to 9·1. Dr. Collingridge furnishes illustrative notes relative to the condition of certain of the cowsheds and he thinks that these notes indicate that at the sources little care is exercised to safeguard the milk-supply, the farmer in the majority of instances taking practically no precautions until he is compelled to do so by some such investigation as is here referred to. Dr. Collingridge considers, however, that there is no real difficulty in getting proper precautions carried out by the local authorities and he sees no necessity for any central authority (presumably the London County Council in this instance) to waste time and money in inspecting farms in the country. We are afraid that he is perhaps a little too optimistic with reference to rural district councils the *personnel* of which is largely made up of farmers. In our view these district councils have done but little except under very great pressure and, as we have said, the improvements made have been largely effected by the milk buyers from London. Our experience of rural district councils in the matter of milk leads us to the conclusion that probably the best solution of the problem is to hand over the control of cowhouses, and so on, to the county councils.

But we are entirely at one with Dr. Collingridge as to the need of further control not only in the condition of the cowsheds but also in that of the cows themselves, in the cleanliness of the milk vessels, and in the matters of transit, of cooling, and of mixing. In our opinion the general cleanliness of cowsheds has materially improved during the last ten years but there is need particularly for more light and ventilation. The average cowkeeper has a distinct bias against light, either because he thinks that it is detrimental to the secretion of milk or less probably because it shows up filth both in the cowhouse and on the udders of the cows. This question of the cleanliness of the cows does not, as a rule, receive sufficient attention, nor does that of the cleanliness of the milkers themselves. The white overalls so often spoken of are not so frequently seen and it is sometimes difficult to discover the "lavatory" in which the milkers are supposed to wash their hands before milking. Despatch of milk in unlocked or unsealed churns is another weak spot in our precautions with regard to milk-supply, and the belief, or excuse, of the farmer that the railway companies refuse locked churns has no basis in fact, although the companies reserve to themselves the right to open locked cans in cases where they suspect that the quantity of the milk is in excess of the declared amounts. Even this may be obviated by marking on the churns their weight when empty. All churns should be locked or sealed and an increasing number of such receptacles seen at railway stations are either fastened with padlocks or sealed with leaden seals. Better provision should be made for securing the scalding by steam of empty milk churns and all mixing of milk at railway stations should be prohibited. This mixing not only involves exposure of the milk but also the use of a "rouser" or mixer, which instrument may at times be found resting upon a dirty platform. Moreover, this mixing enormously accentuates the difficulty of tracing any infection which may have been introduced into the milk, a historical instance of this difficulty being the famous outbreak of scarlet fever in 1885, which was found to be associated with a particular milk-supply derived from a farm at Hendon and which led to Mr. W. H. Power's memorable report. The cowkeeper and the dairyman should make their peace with Mr. Burns at once, for soon he will be within their gates and once there he will be difficult to eject.

to shift for themselves, is true or nearly so throughout the whole lives of women and materially modifies both their standards of right and wrong and their attitude towards the rest of mankind. As a sixpence can be so held as to shut out the view of the sun, so a child, even when grown to maturity, is often an effective screen against considerations which would otherwise be of overwhelming importance or intensity. The great lady who urges the appointment of ALGY or REGGIE to some important military command is not so destitute of imagination as to be unable to picture to herself the disasters which may be caused by his inefficiency; nor is she, as a rule, so stupid as to be under any delusion with regard to his fitness for the function which she exerts herself to secure for him; but he is *her* ALGY or *her* REGGIE, and she therefore desires that he should be placed in a distinguished position, while she trusts to luck and the chapter of accidents to preserve him from disastrous eclipse. His father, in a general way, would be likely to take an entirely different view of the position and its requirements. In the absence of children an anomalous deflection of the female mental vision is sometimes produced by sexual affinities or attractions. There have been few more clear-headed women in history than QUEEN ELIZABETH, but her fondness for LEICESTER occasioned her to shut her eyes to his most disastrous blunders, and only just escaped being the cause of defeat to the United Provinces in their struggle against Spain. There have, of course, been historical examples of evil feminine influences habitually exerted upon otherwise sagacious and far-seeing men, but such examples are comparatively few and the influence when it has been exerted has in most of them been comparatively short-lived. Conditions and circumstances which completely dominate the lives of many women are, as a rule, little more than episodes in the life of man.

Dr. SHAW's observations about what is called "thinking" are eminently worthy of attention and appear to us to deserve a far more prominent place in his discourse than that which has been assigned to them. They strike at the very root of a prevailing popular delusion. He quotes WUNDT as declaring that "people think very little and very seldom," and we entertain no doubt that the common belief to the contrary is mainly due to popular ignorance of the nature of intellectual operations. Assuming them, as they probably are, to be the mere exercise of the special endowments of certain groups of nerve cells, as sensations are the exercise of the special endowments of other groups, it is not difficult to perceive in how large a proportion of cases they are purely reflex phenomena in response to some accustomed stimulus and how soon the habit of responding in some particular way supersedes any original capacity for judging and comparing. At an early period of life the force underlying nervous action may be, and must be, guided, but it soon finds its way into accustomed channels; and the brain of the average "man in the street," when of middle age, is frequently incapable of receiving or of assimilating new ideas. His religion, his politics, his views upon social questions, all tend to become stereotyped, and nothing is more difficult to him than to approach the underlying problems from any new point of view. As time goes on the cell groups which minister to the higher faculties of the mind appear to become atrophied from disuse, and the reconsideration of questions, which has long been difficult, ultimately becomes impossible. We have often thought that the consequent decay of any real power of thinking is an adequate explanation of an immense deal of the early mortality of prosperous middle life. The man of business, the banker or the merchant, learns all about his daily calling by the time when he is 40 and is often content to live in the mere practice, as a matter of habit, of what he has thus acquired. He eats and drinks too much and the higher brain centres waste for want of exercise. He is said to die from gout, or from heart disease, or from kidney disease, but he really dies from stupidity and because there is nothing left to keep him alive. It is highly instructive to compare such examples with those of longevity in men of high intelligence, and we believe it will be found, as a rule, that the latter are furnished chiefly by the callings which require the continued exercise of the intellectual faculties upon comparatively new matter, or upon new combinations of familiar data. Great mathematicians have been proverbially long lived; great judges almost equally so; and it is even probable that something of the same kind might be said for eminent journalists who are constantly called upon to apply their minds to the varying circumstances of the day. We believe that *no* educational acquirement would be of greater value than that which should give the power of restraining the thoughts from perpetual movement along reflex grooves, and should compel them, day after day, if only for some brief season, to consider the foundations of accepted beliefs and the validity of the arguments which might be urged either in defence or in disproof of them. In existing circumstances, the expanse of "gentle dulness" which offers itself to an impartial observer of mankind is not calculated to inspire him with high hopes for either his country or his race.

Annotations.

"Ne quid nimis."

THE HEALTH AUTHORITIES AND THE UNEMPLOYED IN CHICAGO.

COMBINING charitable assistance with the efforts of the local county and municipal authorities a systematic attempt was made to cope with the exceptional distress prevalent during the winter at Chicago. One of the railway companies lent a large brick building and some other premises were available. All new comers, however, spent their first night at the municipal lodging-house where the details concerning their difficulties were properly registered, their clothes fumigated, and their persons bathed. Then they were sent to other institutions for food and lodging. Care was taken not to humiliate these men and they were called upon to work one day out of three and thus to earn the hospitality which they received. The other two days they were to spend in the endeavour to find remunerative employment. The Department of Health instituted an inquiry in view of giving the men relieved all the food which they needed without incurring any unnecessary expense. Thus, the report of the results issued states that while boiled spring chicken gave in gramme calories of food value only 505 units per pound, boiled beef gave 1620 units and bread 1205 gramme calories per pound. The rations given in different obvious cause must be regarded as the subject of trypanosomiasis until the contrary is proved. The gradual onset and development of sleeping sickness are liable to mislead those unskilled in the diagnosis of the disease. The Commissioners in Uganda found, however, that it is possible to divide the course of the ailment into three stages. 1. The stage of fever, during which there are a subtle change of intelligence, febrile symptoms of a hectic type, an accelerated pulse of low tension, and the presence of trypanosomes in the spinal fluid. 2. The stage of tremors. The intelligence becomes more dull, the face puffy, the gait shuffling and uncertain, the speech slow, and the voice high-pitched, and there is a marked tremor of the tongue, the hands, and often of the lips and the legs. During this stage the temperature oscillates. 3. The stage of subnormal temperature and profound lethargy. Inflammatory affections of the respiratory tract are common and secondary bacterial complications are found post mortem, such as purulent meningitis and widespread suppuration of the lymphatic glands; these apparently determine the fatal issue in many cases of sleeping sickness. The duration of the illness is seldom longer than 18 months. The first drug to which value could be assigned in the treatment of sleeping sickness was arsenic and a still further advance was made by the exhibition of trypan-red and afterwards of atoxyl. Treatment by serum, extracts of spleen, injections of cultures of organisms, and the exposure to x rays and other rays have met with little or no success. Curiously enough, benefit, or even the disappearance of the trypanosomes from the blood, occurs by the exhibition of most of the drugs employed. Antimony has been quite recently advocated as a remedy and but for the difficulty of administration it would appear that this drug possesses the power of at least causing the disappearance of trypanosomes. There seems little hope of obtaining a preparation of antimony that can be safely and effectively administered. If given internally it brings on vomiting; by the skin a pustular eruption; and by the hypodermic or intramuscular methods necrosis of the tissues. There is no doubt, however, that a few cases of sleeping sickness may be said to have been "cured" by atoxyl, inasmuch as the patients to whom it has been given are alive and well three years after the disease first showed itself. The trypanosomes of birds, reptiles, batrachians, and fishes are dealt with in Chapters XIV. to XVII., and a great deal of the information in these chapters is added by Dr. NABARRO. The last chapter is concerned with the tsetse flies and their trypanosomes and a coloured plate at the end of the volume shows clearly most of the varieties of trypanosomes at present known.

◆

"The Special Psychology of Women."

THERE is at least this point of resemblance between the man of science and the traditional *sapeur*, that few things are sacred to either. In our columns to-day will be found a lecture, under the above heading, by Dr. T. CLAYE SHAW, in which that very competent authority, greatly daring, addresses himself to a deliberate comparison between the two sexes of which the human race, in common with others, is composed; and arrives, on the basis of such a comparison, at conclusions bearing upon the rightfulness of woman's claim to the electoral franchise. Our admiration of Dr. SHAW's courage is not diminished by the circumstance that his inquiries have led him to take what the ladies who are in sympathy with the current agitation will regard as the right side in the controversy, because the very fact of his doing so on stated grounds implies a definite claim to form an independent opinion and indicates that his decision might have been an adverse one if the data on which it is founded had been different. The suffrage-seeking sisterhood are able to regard with compassion, or, it may be, with contempt, any arguments hostile to their claims which are based upon grounds of political expediency or of social or domestic convenience, because all such are essentially unstable in their character and are liable, or even likely, to be modified greatly by the operations of time and circumstance. The ladies placidly assign the excellence of their education and the amount of their wealth as conditions which entitle them to vote, without reflecting that the privileges of the franchise-possessing males are absolutely independent alike of property and of intelligence. The fact that such an argument is a *non sequitur*, with no bearing upon the question at issue, renders it as irrelevant to one side of the dispute as to the other, and prevents it from being turned with effect against those who use it. But if science, resting either upon physiological data or upon that comfortable word "psychology," had ventured to pronounce an adverse decision, had declared that the sentence "No votes for women" was somewhere, to use the language of PROCHASKA, "written upon the nervous pulp," or that the play of feminine emotions was essentially incompatible with the correct filling up of a voting paper, why, then, we should indeed have been sorry for science, and still more sorry for those who were called upon to give publicity to her conclusions. In some poultry-breeding districts, when a chicken-destroying kite has been caught alive it has been customary to clip its wings, to cut its claws, to stick a cork upon the point of its bill, and then to cast it down among the hens! Imagination shudders at the possible fate of an anti-female-franchise philosopher in like manner surrendered to the vengeance of those whom his pronouncements had converted into enemies.

Our readers will observe, however, that the question of a female franchise occupies only a subordinate place in Dr. SHAW's interesting summary of the essential points of resemblance and of dissimilarity offered to our observation by the two sexes, and that a general view of the whole question leads him to a conclusion which may perhaps be expressed by saying that the resemblances are inherent and absolute, while the differences are artificial or accidental. We are not quite sure of the entire correctness of this view of the case, because it is obvious that maternity is an essentially feminine function; and we regard the most marked and characteristic differences between the sexes as being mainly attributable to its requirements. It may be said of the female animal generally that, when she has young, she does not care whose dinner she takes with which to feed them, and this statement, while it ceases to apply to the lower animals as soon as the young have become able ago there were three, one for each hospital, but the death of Miss M. E. Hayes, M.B., who fell at her post in January of this year, has left but two and these are feeling the severe strain of overwork and responsibility in an Eastern climate. For full particulars, however, of work, salary, the position occupied by the hospitals in question, and other matters as to which detailed information will, no doubt, be desired, reference must be made to the Secretary, Women's Work, S.P.G. House, Tufton-street, Westminster.

LOCALISATION OF FUNCTION IN THE LEMUR'S BRAIN.

At a recent meeting of the Royal Society Dr. F. W. Mott and Professor W. D. Halliburton communicated a paper on the localisation of function in the brain of the lemur which was of distinct interest to medical men. The lemur is the lowest of the ape-like animals and its brain has received hitherto very little attention. The ring-tailed lemur of Madagascar (Lemur catta) was chiefly employed but in two experiments the black lemur (Lemur macaco) was used. The results obtained did not show any material differences between the two species. The investigation dealt mainly with the motor centres and the usual methods of stimulation and extirpation were adopted. In an animal so low in the scale extirpation is more decisive for the purpose of localisation, but in these experiments the results of extirpation have confirmed those obtained by means of stimulation. The course of the degeneration tracts resulting from extirpation was followed by histological examination of the brain and spinal cord. The results agreed remarkably with those obtained by a study of the histological structure of the various regions of the cerebral cortex. Professor Halliburton was responsible for the experimental part of the investigation and Dr. Mott for the histological portion. In all the stimulation experiments the animals were anæsthetised with ether and the anæsthesia was maintained until at the end of the experiment the animal was killed by an overdose of chloroform. The convolution pattern of the lemur's brain is simple; the fissure of Sylvius was easily recognisable but it was not found possible to identify the fissure of Rolando. The precise posterior boundary of the excitable cortex was very difficult to determine with accuracy and it varied in different animals. It is noteworthy that the large motor cells become more and more scattered from before backwards. The trunk and more posteriorly the leg areas are uppermost and extend on to the mesial surface as far as the intercalary fissure. Below this and in front are the various head and face areas. The areas controlling the upper limb are posterior to, and somewhat higher than, these. These excitation experiments show that in the lemurs, as in the primates, there exist three areas, related to the lower limb, upper limb, and head region respectively, from above downwards, in inverse order therefore to the spinal arrangement. The hand and finger area is large in the lemur but this is not remarkable in view of its habits. It does not pick up its food with its hands as a monkey does but it uses its hands to support the morsel which it has picked up with its mouth. The hand movements are, however, undoubtedly more highly developed than in quadrupeds and come chiefly into play in climbing. There is a well-formed and opposable thumb which must be very useful in the arboreal life of the animal. No special thumb area, however, could be found in the cortex. Repeated attempts to evoke eye movements from the occipital pole led to entirely negative results. It is quite certain that this area is, as in other animals, the visual area, for histologically it was found to possess a well-marked line of Gennari. The motor areas were characterised histologically by the presence of Betz cells; localisation by histological study was therefore possible and the results corresponded closely with those obtained experimentally. Two types of motor cortex were found in the lemur's brain. The large type of Betz cell was found in the greater part of the motor cortex, particularly where limb and body movements were represented. The smaller type of Betz cell was found in the area governing face, tongue, ear, and eye movements, and in this excitable region there is a layer of granules; it is therefore probably sensori-motor. The extirpation experiments were performed under ether anæsthesia and with strict antiseptic precautions. Healing took place by the first intention in all cases. The paralysis exhibited after the operation was on the opposite side of the body; it was not pronounced in any experiment and soon passed off. This transitory paralysis has been frequently noticed before, especially in animals low in the scale. The animals were finally killed by chloroform about a fortnight after the operation. It was then found that there had occurred degeneration of the tracts which pass to the bulbar or spinal grey matter which controls these movements. Degeneration also occurred in commissural and association tracts in the cerebrum. The expenses of the research were in part defrayed in grants from the Government Grant Committee of the Royal Society and by the Science Committee of the British Medical Association.

THE STANDARDISATION OF DISINFECTANTS.

At the London School of Tropical Medicine, on April 2nd, Sir Patrick Manson presided at a lecture and demonstration given by Dr. Samuel Rideal upon the Rideal-Walker method of testing and standardising disinfectants. The method is well known to those of our readers who are specially interested in matters of hygiene as it has been before the profession since 1903. We need only say that it consists in preparing different dilutions of the disinfectant to be tested and inoculating them in succession with five drops of a 24-hours' blood-heat culture of a given organism (bacillus typhosus is suggested for standardising purposes) and then taking from each subcultures every two and a half minutes up to 15 minutes. The same process of subculturing is repeated with a 1 per cent. carbolic acid solution. The dilution is noted at which the disinfectant under examination gives the same results for the series as the carbolic control and the lowest dilutions of these two chemical agents which kill the bacteria in equal times stand to each other in the ratio which gives direct numerical expression to their relative germicidal value. For example, if it is found that no growth occurs in subcultures taken from the 1 in 100 carbolic acid solution seven and a half minutes after its inoculation with the organisms, but that five minutes have not sufficed to kill them, and that a dilution of 1 in 1400 of a disinfectant *x* gives the same result, then the Rideal-Walker value of that coefficient is $\frac{1400}{100} = 14 \cdot 0$. The technique is simple and the use of a standard carbolic solution and a standard broth culture minimises the personal equation. In practice, organic matter is added to the solutions in the form of gelatin and starch granules to simulate the conditions of practical disinfection. The authors claim that this method of the carbolic acid coefficient meets in a practical and universal manner the long-felt need of a standard of efficiency on which to base legislation controlling the manufacture and sale of disinfectants. The demonstration was well attended and at its close Dr. David Sommerville, Professor R. Tanner Hewlett, and Dr. Schryver spoke in support of the method. In connexion with this subject we may note that in the House of Commons on April 14th Mr. J. D. Rees asked Sir Edward Strachey, as representing the Board of Agriculture, "whether the Board had made an order to the effect that armies to soldiers in the field were studied, together with the diet of artisans or mechanics while at work. The records of the German Empire are pronounced to have supplied the fairest average. From these investigations it was concluded that a man who was not working required 1800 calories and when in work 3200 calories per day. Therefore the bill of fare was contrived so as to supply, on an average, 3100 calories per day and this was considered enough for men who only worked for six hours every three days. For this they were given bread, butter, coffee, sugar, and molasses for breakfast; bread, coffee, sugar, and a meat stew with vegetables for dinner; bread, coffee, sugar, and a beef or mutton soup thickened with split peas, barley, rice, or beans, turnips, onions, and carrots for supper. Examination of the men as they took their baths showed that 79 per cent. were in normal physical condition, 17 per cent. were overfed, and 4 per cent. only were underfed. The number of unemployed receiving what is described as "emergency lodging-house attendance" during the three months January, February, and March last amounted to 68,328. The Chicago Department of Health states that this experiment has very materially helped to protect the city from contagion, for it has kept the homeless clean, healthy, and free from physical suffering. The inquiries made resulted in forcing out of Chicago some "unworthy, idle, and drifting criminals." On the other hand, some "innately honest but weak men were shielded from being driven into crime." Then it was practically shown that health and strength can be maintained on food that does not cost more than *4d.* per day. It was also demonstrated that lodging-houses can be kept clean, well ventilated, and not overcrowded, giving a bath and sufficient heat, and yield a good profit for less than *5d.* per day per bed. Perhaps, however, the greatest advantage of this method of dealing with the unemployed is that it did not tend to degrade them and to push them down further in the social scale but, on the contrary, gave them ample time to seek for work and to regain their independence.

THE ANTIQUITY OF THE COFFIN.

The shapes of familiar objects of human manufacture do not as a rule excite our curiosity. The box-like form of a coffin, for instance, suggests nothing. Even an undertaker has no views on the *raison d'être* of coffins save that they conduce to decency. Yet on grounds of propriety many nations, such as the ancient Romans and the Hindoos, have preferred cremation to interment, since the latter involves the disfigurement and gradual decay of the dead. Coffins, indeed, are not explainable on grounds of hygiene or seemliness, for which primitive men cared very little. Rather must we see in the modern wooden coffin a copy of the prehistoric stone or chalk receptacle which was a conventional reproduction of one of two things—the mummy cases familiar to students of Egyptology, or the dolmen (or stone house) in which prehistoric non-Aryan races, especially round the Mediterranean from Egypt westwards, were in the habit of burying their dead. Coffins were, as Lord Avebury points out in his "Prehistoric Times," apparently unknown to very ancient man. The dead were buried in a sitting posture or in the attitude of sleep in what were regarded as a kind of ghost houses. The most elaborate and fully differentiated of these houses of the dead are, as Professor Sergi maintains, the pyramids with their mummies and various precautions against the decay of the body. A less elaborate differentiation of the house idea is to be found in the dolmens still remaining all the world over from India to Great Britain. A dolmen, built of five slabs of stone, covered by a tumulus, crowned by a menhir, surrounded by a stone circle as at Stonehenge and Avebury, and led up to by an avenue of standing stones, is, in fact, a rude adumbration of the pyramid. Inside the dolmen the dead sat crouched among cooking utensils, arms, and so forth, put there for their use in the spirit world. Is it too much to suppose that the earliest stone coffins were imitations of the dolmens—in fact, dolmens in miniature? Whether this be so or not, it is very probable that our old-fashioned standing tombstones, and especially our table tombs (which are five-sided), as well as the family vaults of great families with their traditions of embalmment and their leaden shell coffins, which conventionally outline the shapes of the dead within, are so many relics of the remote epoch when a tomb was conceived of as a house in which the dead continued to live their former lives. The leaden shell coffins just mentioned may indeed have originated the modern coffin. The latter has still, for no apparently sufficient reason, to be constructed in accordance with careful measurements and in conventional imitation of the human shape. The leaden shell in the family vault sometimes goes so far as conventionally to preserve the outline of the fingers of the corpse, and this fact would seem to point back to a time when corpses were not coffined. Thus the shell, and afterwards the coffin or elaborated shell, might be regarded as interpolations in the dolmen scheme of burial.

THE DELHI MEDICAL MISSION.

A medical woman desirous of finding an unlimited field for the practice of her profession among members of her own sex, not anxious for material reward, but capable of infinite self-sacrifice, will find a welcome and full scope for all her energies by offering herself at the present time to the Delhi Medical Mission as a member of its staff. Her medical work, should she be accepted, will be performed among native women of India in the neighbourhood of one of the three towns Delhi, Karnal, and Rewari, where the mission has its hospitals, and it will be work done with a view to lighten the burden of physical suffering among women and girls whose fate it is, if unaided, to suffer in a manner undreamt of in this country and almost unrealisable by those who have no acquaintance with the underside of Indian life. In addition to her medical qualifications and to her physical fitness for the life which she will have to live, it will be required of her, as one of the staff of the mission, that she should be a member of the Church of England, ready to feel and to express sympathy with the spiritual as well as with the physical needs of those around her. As a matter of fact, not one but two or three such medical practitioners are required, and of the amount of medical work to be done there would appear to be no limit except that imposed by the physical capabilities of those who have to do it. It includes the treatment of in-patients to the amount of hundreds during the year and of out-patients extending to thousands at the three hospitals, with a still larger number of cases treated outside. These last, it must be remembered, are to be visited in the slums of cities where (to quote from a report of the Karnal Hospital's work) "from long custom it has become a prerogative of the poor and low caste to claim the clothes and even the bed in which their higher class neighbours die. In addition to being infected they are usually in an incredibly filthy condition." This, however, is but an illustration taken at random of the nature of the work, full particulars of which would naturally be obtained first by a lady desirous of embarking upon it, an undertaking not to be entered into lightly. Any such should make early application for information because the need for her services is urgent and she herself would require a short period of preparation as a matter of necessity before being placed in one of the positions now waiting to be occupied. Of the centres named Karnal is situated 70 miles and Rewari 50 miles from Delhi, and in order to allow for necessary leave of absence and to prevent overstrain there should be a full staff of at least five fully qualified medical practitioners. Until a short time process of slow rarefaction. Mikulicz and Henle think that there is produced a hæmatoma, intra- or extra-dural, which compresses the roots and ganglia of the spinal nerves, causing trophic changes which terminate in a kind of vertebral osteomalacia. In 1893 Pierre Marie and Léri made a necropsy in a case of traumatic kyphosis. Almost the whole of the lesions were found between the sixth and twelfth dorsal vertebræ; they consisted in projecting ossification of most of the ligaments, particularly of the common anterior ligament. There were also irregular and incomplete ossification of some of the elastic ligaments and a tendency to union of the spinous processes by ossification of the interspinous ligaments. The pathogenesis of traumatic kyphosis may be deduced from these findings. The sudden bending of the spine produced by a fall on the back or by the fall of a heavy body on the dorsal region ruptures certain ligaments, particularly the common anterior ligament. Kyphosis may immediately result from rupture of important ligaments. But it is generally produced more slowly. The torn ligaments, no doubt, carry with them fragments of periosteum and are repaired by ossification which determines a curve of the affected region that becomes more and more pronounced.

A WORK OF SUPEREROGATION.

THE *Daily News* of April 22nd is responsible for a story from Woolsthorpe in Lincolnshire to the effect that Dr. J. A. Macdonald, the district public vaccinator, has been compelled "to carry a coffin to the grave containing the corpse of an old man who had died from small-pox, all the other residents having refused to go near the coffin." It seems probable that this unpleasant episode has been exaggerated in the telling, for one man could scarcely carry an adult corpse in a coffin unaided from house to grave, and if the devoted public vaccinator wheeled it on a barrow it is not accurate to say that he carried it. However, it seems probable that Dr. Macdonald played a part of conspicuous charity amongst a company of poltroons and he was rewarded in a manner well worthy of the great heart of his neighbourhood. The Grantham board of guardians has appointed another medical man as deputy public vaccinator for Woolsthorpe, "as many people desired to be revaccinated, but were afraid to go near Dr. Macdonald owing to their fear of infection." If the facts of the case have been stated accurately Dr. Macdonald has our sincere admiration for having performed an act which many men even with a keen sense of duty would have refused to carry out, and we can only hope that some reforming spirit may arise in the happily named village of Woolsthorpe who will make the members of that panic-stricken community thoroughly well ashamed of themselves and testify the same by recompensing Dr. Macdonald against any loss of income which his act of devotion may have occasioned him.

MILLON'S REAGENT AS A TEST FOR PUS.

Millon's reagent has been employed as a simple means of differentiating between pus of tuberculous origin and that resulting from the activity of pyogenic organisms by Dr. Eduard Müller.[1] The method recommended is to fill a small deep porcelain dish nearly to the brim with the reagent and to allow a drop of the pus to be tested to fall into the middle of the fluid. If the pus is of tuberculous origin it coagulates to form a firm film, whereas if it is of ordinary character it forms a less tenacious disc. The former can be lifted out on a platinum loop with ease, whereas the latter breaks up into fragments when it is touched by the loop. If the membrane formed by the drop of tuberculous pus be pushed down into the fluid by the loop it takes on a shape like a pea or bean. A further distinction becomes apparent after a quarter of an hour when ordinary pus causes a distinct red staining of the Millon's reagent, while with pus of tuberculous origin the fluid remains quite unstained. The drop of pus becomes red in colour in both cases. The explanation offered of the different results obtained is that the puriform matter from from tuberculous lesions is rich in protein substances which are coagulated by Millon's reagent, whereas with ordinary pus the proteolytic ferment of leucocytic origin converts a considerable proportion of the protein into simpler disintegration products which do not coagulate but which become diffused into the fluid and yield the red colour owing to the presence of aromatic radicles in their molecules. Dr. Lothar Dreyer[2] of Breslau has applied this test in a number of cases with a view to determine its value for surgical purposes in diagnosis. He employed it in 41 cases of ordinary pus and in 32 cases of tuberculous nature, controlling his results in every instance by bacteriological examination. The pus in the first group was produced by such organisms as staphylococci, streptococci, pneumococci, and bacillus coli. In all cases where the pus contained only tubercle bacilli the typical appearances described by Müller were obtained. With ordinary pus the friable disc described was obtained instead but Dr. Dreyer did not always observe the red staining of the fluid. In one instance only did the test leave him in doubt, where the pus from a case of osteomyelitis of the pelvis, which was of very viscid, thick character, gave a result more like the consistence of tuberculous pus. He also found subsequently that pus from a case of mixed infection with tubercle bacilli and pyogenic organisms gave a reaction corresponding to the latter. He is of opinion that the reaction is of considerable value from the little time which it requires and the ease with which it can be carried out. It would appear from Dr. Dreyer's results that the appearance of a thick tenacious film as a result of the test is a strong presumption in favour of the tuberculous origin of the pus, whereas the more friable membrane, although showing the presence of pyogenic organisms, does not exclude the presence of tubercle bacilli.

BOMBAY MEDICAL CONGRESS.

A PRELIMINARY meeting in furtherance of the Medical Congress which it is proposed to hold in Bombay early next year was held at Government House on March 25th under the auspices of the Governor of the Presidency, Sir George Clarke, to whom the credit of initiating the project is due. It was resolved that the following gentlemen, who were all present at the meeting, should form the nucleus of a central committee, which should comprise representatives of all branches of the medical profession in the Bombay Presidency, official and non-official: Colonel R. H. Forman, R.A.M.C., Principal Medical Officer, Bombay; Lieutenant-Colonel C. J. Bamber, I.M.S., Sanitary Commissioner; Lieutenant-Colonel M. Collie, I.M.S., Lieutenant Colonel C. H. L. Meyer, I.M.S.; Lieutenant-Colonel W. E. Jennings, I.M.S.; Major H. E. Winter, R.A.M.C.; Captain W. G. Liston, I.M.S.; Sir Bhalchandra Krishna; Dr. J. A. Turner, Dr. Coghill, Dr. S. A. Powell, and Dr Choksy. The duties of honorary secretary were undertaken by Lieutenant-Colonel Jennings and it was decided that the members of the Governor's council, the surgeon-general with the Government of Bombay, the principal medical officer, Poona Division, and some other distinguished people should be invited to act as vice-presidents of the Congress under the presidency of Sir George Clarke who had consented to accept the post. It was also decided that the drawing up of a definite programme should be entrusted to the central committee which should be asked to give special prominence to sections dealing with the etiology and prophylaxis of tropical diseases, as well as with disinfectants, weed killers, and the like preparations were drugs within the meaning of the Sale of Food and Drugs Act, and whether it was proposed that such disinfectants, weed killers, &c., if sold by others than registered pharmacists, should have a label attached declaring their efficiency in terms of certain recognised standard tests." Sir Edward Strachey in a written answer replied: "The answer to the first part of the question is in the negative. The conditions under which the articles to which my honourable friend refers should be sold are under consideration by a joint committee appointed in connexion with the *Poisons and Pharmacy Bill.*" We believe that general opinion in the medical profession is beginning to hold that there should be some standard of efficiency in disinfectants. For instance, the Central Midwives Board in the regulations issued to midwives[1] lays down that the midwife must take with her to a confinement, amongst other things, "an efficient antiseptic for disinfecting the hands, &c." How is the efficiency in such a case to be measured? and how is the midwife to be sure that she buys "an efficient" antiseptic?

CLASS MORTALITY STATISTICS.

IT is now more than 20 years since Dr. Grimshaw, late Registrar-General for Ireland, began to publish class mortality statistics for the city of Dublin, and in the returns issued by his successor, Dr. Robert E. Matheson, they have been maintained with but slight alteration of form. Having regard to the undoubted influence of class proportion on the rate of mortality in a population, this commendable attempt to throw light on the important but difficult problem of class mortality has scarcely received the attention which it deserves. The tables dealing with this subject in the Yearly Summary of the Irish Weekly Returns for 1907 are valuable and interesting, although the lesson which they teach is no longer new. Dr. Grimshaw, for the purposes of his tables, divided the Dublin population into four classes: (1) professional and independent class; (2) the middle class; (3) artisan class and petty shopkeepers; and (4) general service class. It is obvious that this division into classes must be more or less of an arbitrary character, but the value of the resulting statistics is scarcely thereby affected if the classification of the population and of the deaths is as nearly as possible identical. The Dublin population enumerated in 1901, so divided, included 17,436 of the first class, 87,188 of the second, 110,423 of the third, and 160,303 of the fourth class; the fourth, or general service class, including about 6000 inmates of workhouses. The tables for 1907 show that while the rate of mortality last year did not exceed 16·2 and 17·0 per 1000 respectively in the professional and independent and in the middle class, it was no less than 28·4 per 1000 in the combined classes including artisans, petty shopkeepers, and the general service class. The contrast between the rates of mortality from the principal epidemic diseases was still greater; among the professional, independent, and middle classes the death-rate from these diseases in Dublin during last year did not exceed 0·9 per 1000, whereas it was equal to 2·3 per 1000, or nearly three times as high, among artisans, petty shopkeepers, and the general service class. The bulk of the fatal cases of measles, whooping-cough, and diarrhœa and all the eight deaths from typhus fever occurred in the general service class. From these facts it may safely be presumed that the contrast between the rates of infantile mortality in these class subdivisions would be still more striking, but the Irish summary under notice does not afford the means for calculating class birth-rates or of true class infantile mortality. It appears, however, that whereas the rate of child mortality last year under five years of age did not exceed 37 per 1000 among the professional, independent, and middle classes, it was equal to 89 per 1000 among artisans, petty shopkeepers, and the general service class. While these Irish class mortality statistics are still interesting, as an experiment, it is matter for regret that no attempt has been made to correct these crude rates of class mortality for the widely differing age-constitution of the various class populations, the omission of which affects the value of these crude death-rates for purposes of comparison. These statistics, however, although uncorrected show the necessity for bearing in mind the varying class proportions of different populations when comparing their rates of mortality.

THE DISTRIBUTION OF RAINFALL IN THE BRITISH ISLES.

ALTHOUGH the fickleness of the weather is proverbial, it has long been known that the average rainfall of a country or a locality is to some extent dependent on its geographical position and surface configuration. This sufficiently accounts for the fact that during January and February several lectures on this subject were delivered before the Royal Geographical Society by Dr. H. R. Mill, D.Sc., with special reference to the British Isles, and abstracts of each of these discourses are published in the April number of *Symons's Meteorological Magazine.* Christopher Wren designed in 1662 the earliest rain gauge which has been described, but systematic records of the distribution of rain over the British Isles only commenced in 1860 when the late Mr. G. J. Symons initiated the British Rainfall Organisation and in 1861 published 507 records for the year. The work of this organisation is still carried on in Mr. Symons's former residence, 62, Camden-square, London, where the records collected at 4500 stations are now dealt with every year. The form of rain gauge recommended is either the Snowdon pattern, five inches in diameter, or the Meteorological Office pattern, eight inches in diameter (the two differ only in size), set with the receiving surface one foot above the ground. The highest annual rainfall is always in the neighbourhood of the highest land while the lowest is always on the level plains. The Highlands of Scotland, the Southern Uplands, the Lake District, the Pennine Chain, Wales, the western part of Cornwall and Devon, and the mountains of Ireland all stand out as wet areas, and even the gentle hills of the Eastern Division of England are wetter than the surrounding plains.

TRAUMATIC KYPHOSIS.

AT a meeting of the Société Médicale des Hôpitaux of Paris on April 3rd M. Georges Guillain and M. Guy Laroche reported a case of kyphosis due to a very unusual cause—traumatism. A man, aged 56 years, came under observation with the following history. At the age of 15 years he was well formed and free from any deformity; while going down stairs he slipped and fell on his back. He was taken up and put to bed where he remained for some weeks. Two months after the accident kyphosis began to develop and increased during a year, after which it remained stationary. After the fall the patient felt pains in the spine and subsequently he felt them in damp weather. The deformity did not prevent him from engaging in several occupations—publican, labourer, and hospital attendant. On examination marked kyphosis was seen in the cervico-dorsal region; the culminating point was about the fifth or sixth dorsal vertebra. There was also scoliosis with the convexity to the right and at the back the thorax projected more on the right than on the left side. In front the chest was bulged out and on the left side was in a plane anterior to the right. Different hypotheses have been advanced to explain traumatic kyphosis. Kümmell suggests that some slight attrition of the bodies of the vertebræ is produced and that their nutrition is altered, which causes a errors and to yield an incorrect diagnosis. In normal cases the desmoid reaction occurs in from five and a half to seven and a half hours. When the reaction is retarded or negative it indicates a deficiency of hydrochloric acid or of peptic secretion, or derangements connected with evacuation—e.g., stenosis. When the reaction occurs only after some days pyloric stenosis is indicated. The desmoid test is not absolute but it is capable of rendering great assistance to the physician without causing inconvenience to the patient. It is absolutely innocuous and there are no cases in which it is contra-indicated. In cases of renal or hepatic insufficiency or of derangements of the circulation the rate of elimination of the methylene blue may be affected, thereby introducing possible sources of error, but such cases are not numerous, and when they are met with means can be taken to avoid error.

[1] THE LANCET, August 22nd, 1903, p. 555.

PANCREATIC DIVERTICULA OF THE SMALL INTESTINE.

A good example of the manner in which the international exchange of literature assists medical progress is found in connexion with those obscure structures which, for want of a better name, may be called pancreatic diverticula of the small intestine. These rather uncommon diverticula are usually found in connexion with the third stage of the duodenum but may arise from the upper part of the jejunum. At their cæcal end occurs a glandular mass which is distinctly pancreatic in structure. Mr. H. S. Clogg[1] recently reported a case where such a diverticulum, springing from the third stage of the duodenum of a lad, aged 12 years, became a band under which a loop of intestine was strangulated. Another case is recorded by Mr. H. Alexis Thomson[2] and a number of instances are to be found in recent medical papers published in Austria and in Germany. It is well known that the pancreas is developed as twin buds or diverticula of the duodenum, but Dr. F. T. Lewis and Dr. F. W. Thing,[3] working with human and pig embryos, state that it is quite common to find besides the normal diverticula two or three others, springing from the third part of the duodenum or upper part of the jejunum. Apparently during the course of development they disappear. The cases described by Mr. Clogg and Mr. Thomson are evidently examples in which the embryonic pancreatic diverticula have not undergone retrogression. It is difficult to account for their common occurrence in mammalian embryos, for in no vertebrate animal do accessory pancreatic glands persist in the situation where aberrant diverticula are found to occur. The pancreatic diverticula must not be confused with the form of diverticulum originally described by Dr. H. D. Rolleston, which springs from the inner side of the second stage of the duodenum, just above the opening of the common bile duct. This latter form is quite common, especially in the subjects of enteroptosis, and these diverticula are certainly acquired and not congenital structures.

TUBERCULOSIS OF THE GALL-BLADDER.

Some interesting observations on tuberculosis of the gall-bladder are recorded by Dr. M. Simmonds of Hamburg in the *Centralblatt für Allgemeine Pathologie und Pathologische Anatomie* of March 31st. The patient was a boy who died at the age of nine months from acute generalised miliary tuberculosis. The bronchial and mesenteric glands showed caseous lesions, the ileum and large intestine contained a few ulcers, and there were small tuberculous nodules in all the organs. In the liver, in addition to numerous grey miliary tubercles, there were some larger foci. Some of these were firm in consistence and bile-stained centrally, others were softened so as to present only bile-stained débris, while some were simply small bile cysts. The condition was, in fact, a tuberculosis of the small biliary passages. The gall-bladder was of medium size and was filled with bile of normal appearance in which no tubercle bacilli could be detected. Except for six small areas of the size of lentils, with sharply-defined margins, the mucous membrane of the gall-bladder appeared to be healthy. These areas were more deeply tinged with bile than the surrounding tissues. Microscopical examination revealed some central necrosis in these areas and a zone of granulation tissue around them. Although neither tubercles nor giant cells were found the tuberculous nature of these foci was demonstrated by the presence of numerous tubercle bacilli in the granulation tissues and in the boundary zone between it and the necrotic area. Elsewhere the gall-bladder was free from bacilli. Dr. Simmonds concludes from his observations on tuberculosis of the bile ducts in general that this condition is an excretion tuberculosis analogous to the similar processes occurring in the kidney. He explains the affection of the gall-bladder in this case by supposing that this was brought about by bacilli carried to the gall-bladder from the lesions in the bile ducts, just as tuberculous affections of the pelvis of the kidney may be induced by bacilli which are excreted through the urinary tubules. He further states that since investigating this case he has carefully examined the gall-bladder in all cases of tuberculosis of the biliary passages that have come under his notice and found similar conditions. He is therefore of opinion that tuberculous lesions of the gall-bladder are less uncommon than they are generally supposed to be. He was able to find only six instances recorded in German medical literature, and in these the condition was generally a chronic ulcerative cholecystitis, and in four of them it was also accompanied by cholelithiasis.

The Department of Public Health of Queensland in a bulletin dated March 14th states that a male patient, aged 17 years, died in the Brisbane General Hospital on March 6th and a post-mortem examination showed that death was due to the pneumonic form of plague. Another patient, also a male, aged 18 years, whose death occurred on March 11th, presumably due to plague, was also found on post-mortem examination to have died from the pneumonic form of the disease. Another bulletin dated March 21st states that no further case of plague had occurred at Brisbane during the week ending on that date. A telegram from the Governor of Hong-Kong, received at the Colonial Office on April 27th, states that for the week ending April 25th there were 29 cases of plague reported and 26 deaths from the disease.

The President of the Hospital of St. Cross, Rugby, Mr. R. H. Wood, J.P., D.L., has commissioned Mr. Harrison Dutton to paint the portrait of Dr. Clement Dukes, the senior physician, for presentation to the hospital.

Mr. Joseph Edward Godfrey, M.B., C.M. Edin., Surgeon-General, and Chairman of the Local Government Board of British Guiana, has been appointed a Member of the Executive Council of that colony.

His Grace the Duke of Northumberland will preside at the annual dinner of the Royal Sanitary Institute on May 12th at the Langham Hotel.

The Children's Country Holiday Fund.—We are asked to state that the annual meeting of the supporters of the Children's Country Holiday Fund will be held in the Whitehall Rooms, Hôtel Métropole, on Tuesday, May 12th, at 4 P.M. H.R.H. Princess Alexander of Teck has graciously consented to preside, and the speakers will include the Earl of Errol, Lord Edmund Talbot, and Sir Oliver Lodge. The secretary of the fund is Mr. Wilfrid Blakiston and the offices are at 18, Buckingham-street, W.C.

general sanitation as applicable to India. It was proposed to invite medical men to contribute original papers but that the central committee should have the power of accepting or rejecting contributions. Members attending the Congress would be at liberty to take part in the discussions, the length of their observations being strictly subservient to a time limit. Exhibitions of microscopical and pathological specimens and also of diagrammatic charts and statistical tables would be arranged for; and if possible upon one evening during the session a lantern exhibition of bacteriological and pathological slides would be held. Sir George Clarke in conclusion expressed his thanks to the meeting and assured them that he would do all he could to promote the success of the undertaking. It was his sincere desire and confident expectation that a large amount of practical good would result from a Medical Congress arranged on the lines that had been indicated.

TYPHOID MENINGITIS WITHOUT OTHER LESIONS.

IN the *University of Pennsylvania Medical Bulletin* for April, Dr. R. S. Lavenson has described a condition which appears to be so far unique—typhoid meningitis without other lesions. A woman, aged 26 years, was admitted into hospital on April 22nd, 1906, with intense frontal headache, fever, vomiting, and photophobia. For some weeks she had assisted in nursing her brother in a severe attack of typhoid fever. Four days before admission she was seized with agonising frontal headache with vomiting, photophobia, and great muscular tenderness. These symptoms persisted until admission, when there had been suppression of urine for 36 hours. On examination the temperature was 103° F., the pulse was 80, and the respirations were 16. The patient was slightly stuporous but not delirious and bore an expression of extreme suffering. The forehead was tender on pressure. There was no rigidity of the neck and the knee-jerks were normal, Kernig's sign was not present, there was no eruption, and the spleen was not enlarged. On the 25th she was slightly delirious and Kernig's sign was present. On the 27th the tâche cérébrale was obtained. On the 30th there was rigidity of the neck. On May 3rd hæmaturia occurred and on the 4th œdema of the lungs developed and the patient died. During the first two days of residence in the hospital the temperature varied between 101° and 103·3°; then until death it remained between 99·3° and 102°, fluctuating without any regularity. The leucocytes were about 20,000. On April 23rd Widal's reaction was negative in dilutions of 1 to 10 and 1 to 50; on the 26th it was positive in the same dilution. On the 27th lumbar puncture was performed and the fluid yielded cultures with all the characteristics of the typhoid bacillus. Cultures were made from the blood but proved negative. Except in the meninges the necropsy was negative; there were no intestinal lesions and the spleen was not enlarged. Over the convexity of the right cerebral hemisphere anterior to the pre-marginal fissure was a collection of thick pus in the pia-arachnoid. The ventricles contained light yellow, slightly turbid fluid. Smears from the pus showed a large number of bacilli with the morphological characters of the typhoid bacillus. The complete localisation of the disease to the meninges was probably responsible for the features unlike those of typhoid fever—the leucocytosis, irregular temperature, and absence of rose spots and splenic enlargement. The absence of the Widal reaction until the eighth day of the disease, the usual time of its occurrence in typhoid fever, is noteworthy. Von Leube says: "The occurrence of first a negative and subsequently a positive Widal reaction is the most reliable response to the test. In such case typhoid fever can be positively diagnosed." Cases of meningitis, with serous or purulent exudation, complicating ordinary typhoid fever have been recorded, but none appear to have been recorded in which intestinal lesions were absent. However, Henry and Rosenberger have reported to the Philadelphia Pathological Society a case of typhoid meningitis without intestinal lesions which has not yet been published.

THE DEPARTMENTAL COMMITTEE ON INEBRIATES.

THE Home Secretary has recently appointed a Departmental Committee with the following terms of reference: "To inquire into the operation of the law relating to inebriates and to their detention in reformatories and retreats, and to report what amendments in the law and its administration are desirable." The committee, of which Sir John Dickson-Poynder, Bart., M.P., is chairman, has been constituted as follows: Mr. W. Ryland Adkins, M.P., Mr. T. A. Bramsdon, M.P., Dr. R. W. Branthwaite, H.M. Inspector of Inebriate Reformatories, Mr. W. C. Bridgeman, M.P., Dr. H. E. Bruce-Porter, Dr. H. B. Donkin, one of H.M. Inspectors of Prisons, Dr. C. A. Mercier, and Mr. J. Rose, a metropolitan police magistrate. The secretary of the Commission is Mr. J. F. Henderson, to whom correspondence may be addressed at the Home Office, London, S.W.

THE DESMOID REACTION FOR INVESTIGATING THE FUNCTIONS OF THE STOMACH.

Professor Sahli, of Berne, in 1905 devised a new method for investigating the functions of the stomach, known as the desmoid reaction (δεσμός, a tendon). It depends upon the fact, first noticed by Professor A. Schmidt, that connective tissue is digested and dissolved by the normal gastric juice but not by the intestinal secretions. The method, as described by M. Dubourdieu and M. Lemaire in the *Bulletin des Sciences Pharmacologiques* for March, consists in inclosing a tablet of methylene blue in a membrane of caoutchouc and tying with a catgut ligature to form a small sac, which is swallowed by the patient immediately after the midday meal. Under the action of the gastric juice the caoutchouc remains intact but the catgut is digested more or less quickly, according as the gastric juice is normal or otherwise, with the result that after an interval methylene blue appears in the urine. By observing whether a positive or negative result is obtained, and in the former case whether the time of the appearance of the methylene blue is normal, premature, or retarded, it is possible to arrive at valuable conclusions as to the functional condition of the stomach. In Germany this method has been tried with varying success, owing probably to non-compliance with certain minor but essential details in the technique. The caoutchouc should be of best quality, supple, and about two millimetres in thickness. The catgut should be raw, unsterilised, and 0·3 millimetre in diameter. The methylene blue, weighing about three-fourths of a grain, should be compressed sufficiently to hold it together without being so hard as to hinder it from being quickly dissolved. By following the minute directions given by M. Dubourdieu and M. Lemaire little sacs may be prepared which perfectly inclose the stain, as shown by immersing them for a time in hot water. The appearance of methylene blue in the urine is easily recognised but that of its chromogen is ascertained by boiling the urine with acetic acid. The method has been tried at the Saint André Hospital, Bordeaux, in parallel with that of Ewald, and the diagnostic results obtained have been subsequently confirmed by surgical intervention and otherwise. It is simple, rapid, and capable of clinical control, whereas Ewald's method is complex, prolonged, and largely dependent on the patient. As a result the latter method is liable to involve serious when inner tube was replaced, fan belt loose, &c., all trivial faults but faults which caused a stoppage that need not have taken place. But where possible I advocate being one's own driver. It is much more interesting and in addition much cheaper; chauffeurs as a rule are not as thoughtful of wear and tear, especially of tyres, as owner-drivers. With a lad at 10*s.* a week to do the cleaning it is not only possible but in addition most enjoyable to keep a car in running order, getting a mechanic in, say, once a month to do little jobs, and after a time, if you make a point of watching the mechanic and the way he goes to work, his services may be dispensed with and the job done by the owner himself. A small bench with a vice is soon and cheaply put up, by preference at the back of the motor-shed. And when doing so I suggest a substantial one, with jaws nearly four inches in width. A shelf can be put up for odd tools, such as spanners, pliers, screw-driver, hammers, &c., and with these and a little patience a great deal can be done, and later on if the hobby proves, as I know it will, fascinating, then stocks and dies can be added, and even a lathe, and those that advance as far as this will, I think, even go further and add a small forge. But "go slowly"; it is only waste of money to buy many tools until you really feel the need of them. As I have already said, with only a few spanners much can be done.

About the first job a man learns to do is to take out and clean the sparking plugs, and, oh, what energy is exhibited in making the points bright, but it is as well to remember that the presence of soot there is of no account unless it is sufficient to short or bridge between the live and earthed leads, the common seat of offence being shorting between the central electrode and the shell of the plug and thus no spark at the points. A little petrol or paraffin squirted up the plug and a bit of rag on the end of a darning-needle should soon effect a cure. The plug can then be tested by shorting it on to the engine, joining on the high-tension wire and pulling the engine round, and even then though a good spark at the points results it does not follow that it will do so when in the cylinder under compression, as then the added resistance may cause the spark to pass through small defects in the insulation which it would miss when the pass was easy. It is important to remember to couple up the high-tension wire to a plug when pulling the engine round as otherwise the coil may be damaged by burning the insulation. It is, of course, better to have occasionally to take out and to clean the plugs through over-lubrication than not to have to do so and to have the piston rings squeaking for oil, but there is a happy medium and the engine can be properly oiled without sooting the plugs. It is worth while remembering that if the accumulators are run down and others not procurable it is possible to get the engine to go, so as to get home, by approximating the sparking plug points a bit. The usual gap is one-twentieth to one-sixteenth of an inch. Short circuits are a great source of worry and of roadside involuntary halts. An easy method to detect these torts is to run the engine in the dark; a dull blue flicker soon shows where the leakage is and a little piece of rubber will soon cure the complaint. Personally, I think prevention better than cure, so I have encased each insulated wire on my car in gas rubber tubing, and where they are exposed or likely to rub I have again surrounded them with a lead pipe fixed to the frame, and all the accumulator leads I have brought into a two-inch lead pipe, one end of which is brought through the battery box and then burred over, while the other is fixed to the dashboard. Numbering the leads prior to pushing them through the lead pipe obviates any confusion and is an advantage if a lead has to be followed up. Fibre tubes can also be had and are of use in lieu of the lead pipe.

Of plugs there are no end. The "Poignon," "E. I. C.," and "Oleo" are three among many which rarely give trouble. Personally, I prefer those with china insulation; with a good make cracking of the porcelain rarely occurs, but it is always as well to carry a spare plug. New porcelains are more easily fitted at home than on the road. But because an engine does not fire it does not follow that there is either a short or a diseased plug, the cause may be either at the commutator or the coil. In trembler coils the platinum points may stick as a result of pitting or burning. The treatment in this case will be to remove the screw and trembler blade and dress the points with a small file, so that they are quite true with one another, and then adjust the screw so that a good "buzz" is obtained. In the non-trembler type the screw and trembler at the commutator may need similar treatment and then the screw must be fixed so that there is just room for a thin visiting card to be inserted between the two platinum points. In the wipe commutator fitted with trembler coils, as a result of weakness of the wipe spring, there may not be enough pressure to get good contact when the engine is running quickly, or there may be uneven wear of the fibre with perhaps a ridge near the metal contact, causing the wipe to jump and so miss fire, or the bush of the rocking-piece may be worn so that there is play and consequent want of alignment of the blades with the fibre wheel, or dirt may get in between the two and thus prevent good contact. An inspection soon shows if these morbidities exist; if the wipe spring is weak it can be bent or a new one fitted, or if the roller or block is worn they can be filed true. If the fibre ring or wheel is uneven it should be taken off and spun in the lathe, while any ridge can be taken off with a file. If the bush is worn and time does not permit of a new one being fitted a bit of copper wire makes an excellent washer and will keep the wheel true for a time.

THE BELFAST HEALTH COMMISSION.

THE long-expected report of the Belfast Health Commission, issued as a Blue-book of 150 pages, was made public on April 24th. The commissioners, who were appointed at the request of a deputation of Belfast citizens who waited on the then Chief Secretary of Ireland (Mr. Bryce), consisted of Colonel Thomas Walter Harding, D.L., formerly Lord Mayor of Leeds (chairman); Dr. Archibald Kerr Chalmers, medical officer of health of the city of Glasgow; Dr. Ludovic W. Darra Mair, a medical inspector of the English Local Government Board; Mr. Peter Chalmers Cowan, M.Inst.C.E., chief engineering inspector to the Local Government Board, Ireland; and Surgeon-Colonel David Edgar Flinn, F.R.C.S. Irel., one of the medical inspectors of the Local Government Board, Ireland. These commissioners were appointed to make inquiry and to report as to the following matters in regard to Belfast: "(1) The cause or causes of the high death-rate. (2) The administration by the several authorities charged therewith of all general Acts and Orders relating to the public health and the prevention of disease and of all provisions of local Acts conversant with the same or similar matters, and of all other Acts and Orders, whether general or local, which directly or indirectly affect the public health of the city. 3. The measures they recommend for adoption with a view to the improvement of the health of the city." After a preliminary meeting at Manchester on Feb. 20th, 1907, to discuss arrangements and to settle the order of procedure, the commissioners commenced their sittings in the City Hall, Belfast, on March 5th of that year and terminated them on July 24th, lasting in all 32 days, during which 93 witnesses were examined. They also made personal visits to all localities and places that had any bearing on the health of Belfast and we give below their conclusions and recommendations:—

1. We estimate the population of Belfast for 1906 at about 350,000. The official estimate of the Registrar-General for Ireland (366,220) is, in our opinion, too low, and that based on the method employed by the Registrar-General for England and Wales (397,272) is too high. It is desirable that the methods of framing estimates of population for intercensal years by the Registrars-General for the three divisions of the United Kingdom, should be reconsidered with a view to arriving at such reasonable uniformity as may make possible useful comparisons of vital statistics.

2. The corporation of Belfast, like other local authorities in Ireland, are without information as to the details of deaths occurring in their district, beyond the mere numerical particulars obtained from the Registrar-General's official publications. Such information is of essential importance, for without it a sanitary authority cannot adequately search for or cope with causes of disease and death. We cannot urge too strongly the importance of this matter. The most effective and natural way of dealing with it is to follow the precedent of the English and Scottish Registration Acts, even if such a method involves fresh legislation; and we recommend that this should be done. The proposal to obtain from the Registrar-General for Ireland returns of the deaths ascribed to epidemic diseases and phthisis only we consider to be inadequate.

3. Our examination of a variety of data indicates that the death-rate from all causes in Belfast is, and has been for several years, about the same as that of Manchester, rather lower than that of Dublin or Liverpool, but not so low as that of other large cities of the United Kingdom. Although the death-rate of Belfast from all causes is by no means low, we think the allegation that it is, or has been in recent years, excessive, cannot be maintained.

4. On the other hand, mortality in Belfast from certain causes, notably from enteric fever and from phthisis, and to a less extent, from diseases of the nervous system, has been excessive.

5. Although Belfast holds a not unfavourable place among other large cities in regard to infantile mortality, the death-rate among the

MOTORING NOTES.

By C. T. W. Hirsch, M.R.C.S. Eng., L.R.C.P. Lond.

THE Motor Union of Great Britain and Ireland has appointed from among its members the following committee of medical motorists to protect the interests of the general body of medical men using motor-cars and to advise the Motor Union on all matters in which the interests of medical men as motorists are particularly concerned:—Mr. C. B. Lockwood (London), Mr. W. Watson Cheyne (London), Mr. J. C. Barker (Watford), Dr. Lovell Drage (Hatfield), Mr. E. L. Rowe (Ipswich), Mr. C. B. Moss-Blundell (Thornton Heath), Mr. S. R. Russell Matthews (Peckham), Mr. J. R. Benson (Bath), Mr. W. J. Gilpin (Bourne), Dr. W. F. R. Burgess (Streatham), Mr. L. A. Bidwell (London), Dr. J. Lewis Lock (Uxbridge), Mr. E. W. Marshall (Mitcham), Mr. W. E. C. Musson (Hammersmith), Mr. J. Hopkins Walters (Reading), Dr. P. P. Whitcombe (London), Dr. C. Buttar (London), Mr. H. Myddelton-Gavey (Eastbourne), Dr. C. R. M. Wood (Woolpit), Dr. B. Holroyd (Pannal), Mr. A. T. Falwasser (Maidstone), Mr. F. T. Travers (Maidstone), Mr. G. Horatio Jones (Deddington), Mr. A. Lindow (Plumstead), Dr. Priestley Leech (Halifax), Dr. D. J. Mason (Maidenhead), and Dr. A. Page Robertson (Glasgow). At a meeting held at the offices of the Union, 1, Albemarle-street, Piccadilly, London, W., Mr. C. B. Lockwood was unanimously elected chairman of the committee and Dr. J. L. Lock vice-chairman. The question of the position of medical men in reference to the proposed taxation of motor-cars was considered and it was resolved that a letter should be sent to the Chancellor of the Exchequer, signed by all members of the committee, embodying the following resolution:—

> That in the opinion of medical motorists any additional taxation upon motor cars would not be equitable and would press with special severity upon medical men who use motor vehicles to enable them to carry out their professional duties.

The new charges of the Metropolitan Water Board for water for washing cars were considered and it was resolved that the proposed charge of 20*s.* per car per annum was excessive and unfair as compared with the rate for water for horse carriages and it was resolved to approach the Board upon the matter.

However good a pneumatic tyre may be there is always the possibility—and the pessimist will say the probability—that a nail or a sharp flint may puncture it, and then delay occurs. Punctures which happen when an urgent case is awaiting one are serious. It is true the Stepney wheel will save the situation to an extent, but doctors will, I know, welcome a tyre that cannot puncture and a tube which, as long as it is covered by a cover, lasts—well, almost for ever. Such is what the "Elastes"-filled tube is claimed to be. And so convinced are the Elastes Company of the efficiency of their invention that they recently submitted a 18 h.p. Siddeley car, fitted with elastes-filled tubes on the wheels, to a 3000 miles trial under the Royal Automobile Club's observation. Knowing my interest in these matters the company kindly offered me a seat on the car while the trial was on. For nearly four years I ran a car on solid tyres; my nerves still remember the bumps, and my banking book reveals from the cheques then drawn for repairs, the costs of solids, not for the tyres, but for differential gears or sleeves that gave out as a result of "solid tyres." So it was in a very sceptical mood that I turned my pneumatic-tyred car out at the early hour of half-past seven one morning and drove to the Royal Automobile Club garage in Down-street, Piccadilly. There I left the air-filled tube car and in company with the Automobile Club observer and the representative of the Elastes Company mounted what I erroneously thought must be a solid-tyred vehicle. We had 150 miles to do, and though some of the roads we travelled over were really bad, especially in London, and some further out were stone-covered and unrolled, still I could not tell that we were not riding on air-filled tubes. In addition, it did not seem to alter our speed. The 18 h.p. Siddeley can do its 40 miles an hour. We had a speed indicator on the car, and if it read correctly (and I believe it did) we at times exceeded 40, and certainly there seemed to be no difference in the running either as regards speed, comfort, or resiliency. The question then occurred to me whether, although one did not feel any discomfort, it caused more jar to wheels or to the machinery, especially the transmission gear. The car in question has a live axle and a metal-to-metal clutch, and had done over 2000 miles of the test when I had my run; all that time it had been in charge of the club officials and had not needed any repairs at all. With solid tyres, though the car is, I know, of good make, still I think with a metal-to-metal clutch and a live axle something would have given work to the repairers; and the fact that no repairs had been needed, and that as far as I could tell the machinery was perfect, shows, I venture to think, that elastes-filled tyres give as great protection to the machinery as pneumatic tyres. The spokes of the wheels seemed to be perfectly tight, although on my solid-tyred car, after some thousand miles, they became a bit loose.

Having thus had actual proof that this "stuffing" was of use, I thought I would find out something about its composition. Well, it looks like the patent substance used for filling pessaries, stuff that is supposed not to harden and to keep the instrument soft. For all I know it may be the same material; it consists of glue, glycerine, and chromate salts; these are mixed in a hot state and then forced into an ordinary inner tube, which has a valve to let the mixture in and another to let the air out; these tubes, or *boyaux* as they are called, are placed in a special cover, which is really a mould, and then subjected to a pressure which varies according to the weight and horse-power of the car the *boyau* is intended for, then the valves are removed, the tube is sealed, and set aside for the contents to solidify, and after a period of about ten days it becomes a solid resilient mass. As a result of experience the makers only fit their speciality on their moveable flange rims, as with ordinary rims there may be irregular bedding of the cover bead in the rim flange and thus damage to the filling. Their rim is very simple, merely an ordinary rim from which one flange has been removed; this is fixed to the wheel, the cover with the *boyau* inside is put on, then the moveable flange is put on, and the two are held together by bolts that pass through the felloe, and so that wet shall not enter, there is a groove on the lower part of the felloe, into which a rubber ring fits, and against this the moveable flange presses. The makers, I understand, undertake to convert customer's wheels to take this rim, plugging the ordinary valve and securing bolt holes. They only insist on having the cover, for which the elastes is needed, as if the *boyau* is not a perfect fit it will wear badly or even be damaged. If the cover is sent to them they will mould the *boyau* to it, and as long as care is taken to remove any nails or other matter which may have penetrated the tube, and the cover really covers the tube, then the elastes-filled tube can be used over and over again. They have fitted no less than five covers over one elastes-filled tube and they are of opinion that the tube is no nearer its end than on the day it was first fitted.

The official observer very kindly allowed me to see a variety of horse-shoe and other nails that had been found in the tyres after some of the daily trips and after the journey which I had a long nail was withdrawn which would have surely punctured a pneumatic tyre but had had no effect on elastes. As a result of my day's outing I have made up my mind that when I need new tyres I will have elastes, and I seriously counsel all of the profession investing in cars to have a run on a car so tyred and to experience for themselves how impossible it is to tell the difference between tyres so filled and pneumatics. It can be used with any covers.

Mr. Duckham, in a recent number of the *Motor Car Journal*, outlined a bonus scheme for chauffeurs which seemingly he has found to answer well. As he remarks, delays mean loss of money and unpunctuality, quite apart from the ordinary annoyance of being hung up, and this is especially so with the profession, so for those who have neither time nor inclination to do their own driving and who have professional chauffeurs his plan is certainly worth trying. His agreement with his man was that in addition to a fixed pay he was to have £30 at the end of 12 months, on the conditions that 2*s.* 6*d.* was deducted for every time the car was stopped on the road by any trouble which could have been avoided had the car received proper attention in the motor house, and in addition every time on the road any sign of omission was observed, which though it did not cause a stop might have done so. His man lost 17 half-crowns in the year, the causes of the stoppages being petrol-jet blocked, omission to fill up petrol tank, forgetting to replace cap on valve of the front off tyre, leakage of gas from acetylene gas generator, no paraffin in side lamp, pliers forgotten, magneto terminal loose, chalk forgotten

Dinajpur district. At Jalpaiguri the fever mortality was so high as to cause the Duar Planters' Association to memorialise the local government for the appointment of a commission to inquire into the fevers of the Duars, which were seriously threatening the prosperity of the tea industry. The association also asked for an inquiry into the causation and treatment of blackwater fever, which has also lately become alarmingly prevalent amongst the Europeans. The government is considering this memorial and we trust that the application of the Planters' Association may attain its object speedily, for the death-rate does not abate during "considerations." The sanitary condition under which the coolies and employers live is evidently not perfect, for the coolie lines are insanitary villages run up without any attempt at regularity or order and are crowded with a fever-stricken population, remaining year by year practically without control or medical treatment. The endemic fever index has been reckoned on some gardens as high as 74·83 per cent. Rangpur, again, is another district in which the heavy mortality from fever is notorious. The Deputy Sanitary Commissioner, Captain O. A. Gourlay, I.M.S., was deputed to make a local inquiry and found various sources for the unhealthiness. As the result of his inquiry a scheme has been sanctioned whereby the drainage of the whole area of the *bhil* country will be improved.

Kala-azar showed much less incidence during 1906, there being 623 cases less than in 1905. Not a single case was found on the banks of the Darrang river in the Garo Hills, the home of the disease. Bowel affections showed a death-rate of 0·90, compared with 0·74 per 1000 the decennial ratio. Several outbreaks of plague occurred in the province in 1906. Nearly all the cases of the severe epidemics which have occurred here have been of the pneumonic variety; in fact, only one example of the bubonic class has occurred, namely, at Dibrugarh; the latter appeared to have been connected with granaries and infected rats, whereas this was not the case as regards the pneumonic cases.

This interesting report concludes with some observations on the sanitary work of the province and some general remarks. Amongst the latter the paragraphs concerning the sale of quinine are worthy of attention. Depôts are now opened at each headquarter station under the direction of the civil surgeon and the price of the drug is reduced. During 1906 there has been a considerable increase in the number of packets issued to the population—2094, in contradistinction to 1021 in 1905. To popularise the remedy in a greater degree it is being issued as sugar-coated quinine tablets and leaflets in the vernacular are being distributed telling the story of the malarial fevers. Special hospital assistants for the distribution of the remedy are also recommended. The report concludes with a series of appendices of vital statistics.

United Provinces of Agra and Oudh.

The thirty-ninth annual report of the Sanitary Commissioner for the United Provinces of Agra and Oudh for 1906 comes from the pen of Lieutenant-Colonel S. J. Thomson, I.M.S. In the first place, we here note that the birth-rate was below, and the death-rate above, the normal. With respect to the history of the chief diseases, the following facts are recorded. Cholera caused a larger number of deaths than in 1905 and in the quinquennial mean, the death-rates being respectively 3·14, 2·55, and 1·07 per 1000, the largest number occurring in May and the smallest in January. All the districts suffered more or less from the disease in the year under report. Small-pox also showed an increased mortality, there having been 13,202 deaths, as against 3273 in 1905, the death-rates being 0·28 and 0·07 respectively. Plague fortunately was much less prevalent, there being 69,660 deaths in 1906 as compared with 383,802 in 1905, the rates being 1·46 and 8·05 respectively. Fevers showed an increase in the number of deaths, the death-rates for 1906, 1905, and the quinquennium being 27·62, 26·92, and 25·29 respectively. There was a very severe and widespread epidemic from September until the close of the year, no less than 43·7 per cent. of the total cases occurring during this period. The anti-malarial measures consisted in improving the surface drainage and filling up hollows and excavations. Measures to destroy mosquitoes and their larvæ were only undertaken on a limited scale and in a few districts. The quantity of quinine sold at the various agencies showed a very satisfactory increase, the number of packets of powders being 1,205,181, as compared with 643,668 in 1905. Dysentery and diarrhœa gave a less return than in 1905, the death-rates having been for these years 0·55 and 0·56 per 1000 respectively; the quinquennial average is 0·61. Here, again, the largest number of deaths took place in May. Respiratory diseases gave a return of 20,139 cases, against 23,271 in 1905, but the Sanitary Commissioner considers the mortality to have been understated owing to this heading having only been recently included in the return. January gave the greatest mortality. The report deals likewise with the civil sanitary works, from which it is seen that great attention is being paid to the disposal of the sewage. The various analyses of the water-supply were satisfactory. The Sanitary Commissioner in his concluding remarks states that 1906 is shown to have been an unhealthy year. Mortality was higher from malarial fever, cholera, small-pox, and measles, although considerably lower as regards plague. This is probably the last sanitary report that this able officer will write and he well deserves the recorded appreciation of his services by the Lieutenant-Governor of the province—services which have been rendered for the last 11 years.

Punjab.

Lieutenant-Colonel C. J. Bamber, I.M.S., is responsible for the sanitary report of the Punjab for 1906. It is very satisfactory to note that the death-rate for 1906 exhibits a very substantial decrease of 10·61 per 1000 as compared with that of 1905, the respective ratios being 36·94 and 47·55 per 1000. For this diminution the lessened mortality from plague is chiefly responsible. For the first time also since 1901 the birth-rate exceeds the death-rate. With regard to the causes of mortality, that from fevers was rather greater than in 1905, 407,878 deaths being registered from this cause, or more than half the mortality from all causes. Yet the year 1906 was not particularly unhealthy in this respect, for the death-rate from this class of disease was below the average for the previous five years. Cholera was more prevalent than in the year preceding but the death-rate was very small, only 0·21 per 1000. The total deaths numbered 4232. The disease was reported from all the districts, the largest number occurring in that of Lahore. Its seasonal prevalence followed the usual course, being mostly present in July, August, and September. Small-pox accounted for a rate of 0·66 per 1000, which is 0·43 more than in the previous year and 0·18 in excess of the mean rate of the preceding quinquennium. But although the actual number of deaths registered must be considered very excessive compared with that shown by all civilised countries where vaccination is carried out thoroughly, yet not only was the death-rate in the Punjab very much higher in former years when vaccination was less thoroughly carried out, but also it is to be noted that during the last 40 years, since the introduction of the system of death registration in 1867, there has been a successive reduction of the disease in each decennium.

With regard to plague the most marked feature of the year was the diminution in plague mortality, which fell to the lowest figure recorded since 1901, there being 91,712 deaths reported, as compared with 334,897 in 1905. This lessening of the mortality might encourage the idea that a natural decline of the epidemic had begun but there is no evidence to support such an assumption, for at the end of the year plague was as bad as ever. The people of the province, although generally apathetic, are gradually becoming less suspicious of proffered assistance. By far the majority of the cases were bubonic with a certain number of pneumonic and comparatively few septicæmic cases. The case mortality in the British districts was 87 per cent., no general diminution in virulence being apparent. With regard to the present plague policy that is pursued, this is based primarily on the recognition of the fact that the annual seasonal epidemics lasting from autumn to spring depend chiefly on recrudescences in a large number of places and spreading from these over the surrounding country. Hence the primary importance of preventing these recrudescences: this is a matter of much difficulty due to the impossibility of discovering definitely every endemic centre, whilst they must be attacked before infection becomes active, which makes the time available for the operations very short. The work is then so enormous that plague will break out in many places before all, or even a number of, the endemic centres have been treated. The operations in 1906 have, however, been fairly successful in stamping out recrudescence or in causing comparative freedom from the disease. Evacuation was found to be the most effective measure; disinfection is not of so much advantage as it is but rarely that information is other young age groups of the population appears to have been excessive in Belfast. The causes operating to produce this relatively high mortality at these young ages should be thoroughly investigated.

6. The mean annual mortality from enteric fever has been so exceptional in Belfast for the last 25 years that it appears to have no parallel in any other city or large town in the United Kingdom. Insanitary conditions have no doubt played a very important part in fostering enteric fever in Belfast, but cannot of themselves account for so excessive a mortality from this disease or for other features of its history. The water-supply cannot account for fever in Belfast, because there has been no relation between the distribution of the disease and the distribution of any one of the three separate sources of water-supply. On the contrary, the incidence of fever on different parts of the city has been generally similar and simultaneous, irrespective of water-supply or insanitary conditions, and moreover it appears to have almost exclusively affected the working-class areas of the city. Neither can the constant excess of enteric fever in Belfast be attributed to the local and occasional outbreaks which have been traced to infected milk. On the other hand, the known features of the history of Belfast fever are consistent with an explanation attributing them to the influence, direct and indirect, of shell-fish gathered from the grossly contaminated foreshores of Belfast Lough.

7. No system of sewage treatment, within practicable limits of cost, will fully safeguard the lough shell-fish, and we are of opinion that powers should be obtained to prohibit the gathering of these shell-fish for human consumption.

8. Mortality referred to phthisis and other tuberculosis diseases has been, and is, excessive in Belfast in comparison with English and Scottish cities, but it has not been exceptional for an Irish city. Since 1895 there has been some diminution of it in Belfast. The age and sex incidence of phthisis mortality in Belfast and Ireland is very different from what it is in Manchester and in England and Wales. It may to some extent be due to differences in disease nomenclature in the two countries. The whole question of phthisis in Ireland seems to us to require further and exhaustive inquiry.

9. We have refrained from any recommendations in regard to the notification of phthisis and the provision of sanatoria or dispensaries, as the Local Government Board for Ireland have advised local authorities in recent circulars, and we understand that a Bill on these subjects is about to be introduced by the Chief Secretary for Ireland.

The report with its severe strictures and its numerous recommendations thoroughly justifies the action of the citizens and of the medical profession who, in the interests of their city and of public health, demanded the inquiry. We propose to discuss some of the features of the report in a future article.

SANITARY REFORM IN INDIA.

VII.[1]—THE ANNUAL SANITARY REPORTS.

THE annual reports of the authorities responsible for the sanitation of the various provinces of India for the year 1906 deal with an immense amount of material in connexion with Bengal, Eastern Bengal and Assam, the United Provinces, the Punjab, the Central Provinces and Berar, Burma, the North-West Frontier, Bombay, and Simla.

Bengal.

The thirty-ninth annual report of the Sanitary Commission for Bengal for 1906 is issued by Lieutenant-Colonel F. O. Clarkson, I.M.S., the Sanitary Commissioner for that province. It deals comprehensively with the facts relating to the meteorology of the year, the vital statistics, the history of the chief diseases and of vaccination, the sanitary works, and the work of the Sanitary Board. With respect to the meteorological facts, the rainfall was remarkably heavy during the cold season months; that of February established an absolute record, the number of rainy days being three or four times greater than usual; in contradistinction to this the monsoon period generally gave but a scanty rainfall with irregular distribution, and the public health was thereby affected and was worse in 17 districts. The vital statistics showed a falling off in both the number of births and deaths recorded, amounting to 116,268 in the case of the former and 114,439 in that of the latter. The reduced birth-rate was evidently due to the general unhealthiness of the year 1905 and to the prolonged continuance of high prices of food grains everywhere, which, by lowering the vitality of the people, acted as a check on the growth of the population. As regards the deaths, the decrease was due to the comparatively smaller mortality from plague and fever.

Coming next to the history of the chief diseases, we find that there were a much extended prevalence of, and a serious rise in the mortality from, cholera, there having been 192,596 deaths, as compared with 116,490 deaths the average mortality of the five years 1901–05, the respective ratios being 3·81 and 2·33 per 1000. In fact, never since 1900, when the cholera mortality was the highest ever recorded, has there been such a heavy loss of life from this cause. The mortality was highest in the province as a whole during April and May and lowest in February and January. The death-rate from small-pox was more than thrice as large as in the preceding year, the ratios being respectively 0·43 and 0·14 per 1000. With respect to plague there was a very satisfactory reduction, the total deaths being 59,619, against 126,084 in the preceding year, the ratios corresponding being 1·17 and 2·52 per 1000. A larger percentage of females perished than of males. During the year under report 1777 antiplague inoculations were performed, against 1544 during the preceding year. No cases of, or deaths from, plague were reported anywhere amongst the inoculated. The disease was most prevalent during the first four months of the year, there being then considerable coolness and excessive rains, whilst with the onset of the hot weather there was a sudden drop in the mortality. With regard to the means undertaken for its suppression chemical disinfection was carried out in special cases where it was asked for and in several municipal areas where it could be supervised. Disinfection by heat and examination of infected houses became very popular. At Barari a knapsack sprayer was used to spray the inside of infected houses with kerosene oil emulsion and was attended with signal success. Lastly, rat-killing is seen to be gradually becoming popular. In Jaghdispur this was carried on in a systematic way and the town enjoyed complete immunity from the disease, whilst the latter recrudesced and prevailed with much severity in adjoining thanas and nearly all the other towns in the district. Fever prevailed with somewhat less severity than in 1905, there being 1,126,315 and 1,214,487 deaths respectively. Antimalarial measures were carried on in certain districts, such as filling in hollows and depressions, clearing jungles, and spreading kerosene oil on all foul tanks and cesspools, and in one place quinine was distributed free as a prophylactic. Dysentery and diarrhœa caused 1809 more deaths than in 1905. The report concludes with the sections relative to sanitary works and the annual report of the Sanitary Board, Bengal, for 1906, together with the various appendices relating to the above facts.

Eastern Bengal and Assam.

Lieutenant-Colonel E. C. Hare, I.M.S., the Sanitary Commissioner for Eastern Bengal and Assam, furnishes the report for the year 1906 for this province. Here the district reports did not record any severe waves of cold or heat and the rainfall, evenly distributed over the land, was neither markedly excessive nor deficient. The high prices for grain and its scarcity, which had prevailed in 1905, continued also in 1906, but on investigation, although in some districts the scarcity was undoubtedly due to heavy and prolonged floods at the time when the rice crop was growing, elsewhere it seems to have been due rather to excessive exports of grain and to a limitation of the area under rice cultivation, owing to an increase in the demand for jute and the high price realised by its cultivation; but whatever were the causes of the scarcity, there is no evidence that the high price had any marked effect on the general health of the people, the provincial death-rate being approximately the same as it had been during the last five years and that from bowel complaints being only slightly in excess of the decennial rate. The provincial birth-rate was 37·38, as compared with the quinquennial rate of 39·63. The death-rate was 31·67 for the year, practically the same as that of the previous five years—viz., 31·66—and much lower than that for 1905, which was 35·06, this decrease being chiefly due to a lessened mortality from fevers. The chief causes of mortality were found to be fever, cholera, dysentery, diarrhœa, and small-pox. With respect to cholera the provincial death-rate was higher than that of the decennial average, although lower than that of 1905, the ratios being respectively 3·63, 2·45, and 4·77 per 1000. In the account of the causation we note the drinking of contaminated water as the immediate cause of the outbreaks, so much so that the people are at length beginning to realise the necessity of having good water and applications for grants for improving the existing tanks, making new ones, and sinking wells are numerous. Almost all the civil surgeons who have had to do with the epidemic outbreaks report very favourably on the preventive method of treating the water-supplies with permanganate of potassium.

With respect to the returns for fever, the rate was lower by 1·90 per 1000 than that of the last ten years, although it was high in certain individual towns and rural areas, such as the

---

[1] Nos. I., II., III., IV., V., and VI. were published in THE LANCET of Feb. 22nd (p. 582) and 29th (p. 631), March 14th (p. 806) and 21st (p. 855), and April 11th (p. 1101) and 25th (p. 1223), 1908, respectively.

Dinajpur district. At Jalpaiguri the fever mortality was so high as to cause the Duar Planters' Association to memorialise the local government for the appointment of a commission to inquire into the fevers of the Duars, which were seriously threatening the prosperity of the tea industry. The association also asked for an inquiry into the causation and treatment of blackwater fever, which has also lately become alarmingly prevalent amongst the Europeans. The government is considering this memorial and we trust that the application of the Planters' Association may attain its object speedily, for the death-rate does not abate during "considerations." The sanitary condition under which the coolies and employers live is evidently not perfect, for the coolie lines are insanitary villages run up without any attempt at regularity or order and are crowded with a fever-stricken population, remaining year by year practically without control or medical treatment. The endemic fever index has been reckoned on some gardens as high as 74·83 per cent. Rangpur, again, is another district in which the heavy mortality from fever is notorious. The Deputy Sanitary Commissioner, Captain C. A. Gourlay, I.M.S., was deputed to make a local inquiry and found various sources for the unhealthiness. As the result of his inquiry a scheme has been sanctioned whereby the drainage of the whole area of the *bhil* country will be improved.

Kala-azar showed much less incidence during 1906, there being 623 cases less than in 1905. Not a single case was found on the banks of the Darrang river in the Garo Hills, the home of the disease. Bowel affections showed a death-rate of 0·90, compared with 0·74 per 1000 the decennial ratio. Several outbreaks of plague occurred in the province in 1906. Nearly all the cases of the severe epidemics which have occurred here have been of the pneumonic variety; in fact, only one example of the bubonic class has occurred, namely, at Dibrugarh; the latter appeared to have been connected with granaries and infected rats, whereas this was not the case as regards the pneumonic cases.

This interesting report concludes with some observations on the sanitary work of the province and some general remarks. Amongst the latter the paragraphs concerning the sale of quinine are worthy of attention. Depôts are now opened at each headquarter station under the direction of the civil surgeon and the price of the drug is reduced. During 1906 there has been a considerable increase in the number of packets issued to the population—2094, in contradistinction to 1021 in 1905. To popularise the remedy in a greater degree it is being issued as sugar-coated quinine tablets and leaflets in the vernacular are being distributed telling the story of the malarial fevers. Special hospital assistants for the distribution of the remedy are also recommended. The report concludes with a series of appendices of vital statistics.

United Provinces of Agra and Oudh.

The thirty-ninth annual report of the Sanitary Commissioner for the United Provinces of Agra and Oudh for 1906 comes from the pen of Lieutenant-Colonel S. J. Thomson, I.M.S. In the first place, we here note that the birth-rate was below, and the death-rate above, the normal. With respect to the history of the chief diseases, the following facts are recorded. Cholera caused a larger number of deaths than in 1905 and in the quinquennial mean, the death-rates being respectively 3·14, 2·55, and 1·07 per 1000, the largest number occurring in May and the smallest in January. All the districts suffered more or less from the disease in the year under report. Small-pox also showed an increased mortality, there having been 13,202 deaths, as against 3273 in 1905, the death-rates being 0·28 and 0·07 respectively. Plague fortunately was much less prevalent, there being 69,660 deaths in 1906 as compared with 383,602 in 1905, the rates being 1·46 and 8·05 respectively. Fevers showed an increase in the number of deaths, the death-rates for 1906, 1905, and the quinquennium being 27·62, 26·92, and 25·29 respectively. There was a very severe and widespread epidemic from September until the close of the year, no less than 43·7 per cent. of the total cases occurring during this period. The anti-malarial measures consisted in improving the surface drainage and filling up hollows and excavations. Measures to destroy mosquitoes and their larvæ were only undertaken on a limited scale and in a few districts. The quantity of quinine sold at the various agencies showed a very satisfactory increase, the number of packets of powders being 1,205,181, as compared with 643,658 in 1905. Dysentery and diarrhœa gave a less return than in 1905, the death-rates having been for these years 0·55 and 0·56 per 1000 respectively; the quinquennial average is 0·61. Here, again, the largest number of deaths took place in May. Respiratory diseases gave a return of 20,139 cases, against 23,271 in 1905, but the Sanitary Commissioner considers the mortality to have been understated owing to this heading having only been recently included in the return. January gave the greatest mortality. The report deals likewise with the civil sanitary works, from which it is seen that great attention is being paid to the disposal of the sewage. The various analyses of the water-supply were satisfactory. The Sanitary Commissioner in his concluding remarks states that 1906 is shown to have been an unhealthy year. Mortality was higher from malarial fever, cholera, small-pox, and measles, although considerably lower as regards plague. This is probably the last sanitary report that this able officer will write and he well deserves the recorded appreciation of his services by the Lieutenant-Governor of the province—services which have been rendered for the last 11 years.

Punjab.

Lieutenant-Colonel C. J. Bamber, I.M.S., is responsible for the sanitary report of the Punjab for 1906. It is very satisfactory to note that the death-rate for 1906 exhibits a very substantial decrease of 10·61 per 1000 as compared with that of 1905, the respective ratios being 36·94 and 47·55 per 1000. For this diminution the lessened mortality from plague is chiefly responsible. For the first time also since 1901 the birth-rate exceeds the death-rate. With regard to the causes of mortality, that from fevers was rather greater than in 1905, 407,878 deaths being registered from this cause, or more than half the mortality from all causes. Yet the year 1906 was not particularly unhealthy in this respect, for the death-rate from this class of disease was below the average for the previous five years. Cholera was more prevalent than in the year preceding but the death-rate was very small, only 0·21 per 1000. The total deaths numbered 4232. The disease was reported from all the districts, the largest number occurring in that of Lahore. Its seasonal prevalence followed the usual course, being mostly present in July, August, and September. Small-pox accounted for a rate of 0·66 per 1000, which is 0·43 more than in the previous year and 0·18 in excess of the mean rate of the preceding quinquennium. But although the actual number of deaths registered must be considered very excessive compared with that shown by all civilised countries where vaccination is carried out thoroughly, yet not only was the death-rate in the Punjab very much higher in former years when vaccination was less thoroughly carried out, but also it is to be noted that during the last 40 years, since the introduction of the system of death registration in 1867, there has been a successive reduction of the disease in each decennium.

With regard to plague the most marked feature of the year was the diminution in plague mortality, which fell to the lowest figure recorded since 1901, there being 91,712 deaths reported, as compared with 334,897 in 1905. This lessening of the mortality might encourage the idea that a natural decline of the epidemic had begun but there is no evidence to support such an assumption, for at the end of the year plague was as bad as ever. The people of the province, although generally apathetic, are gradually becoming less suspicious of proffered assistance. By far the majority of the cases were bubonic with a certain number of pneumonic and comparatively few septicæmic cases. The case mortality in the British districts was 87 per cent., no general diminution in virulence being apparent. With regard to the present plague policy that is pursued, this is based primarily on the recognition of the fact that the annual seasonal epidemics lasting from autumn to spring depend chiefly on recrudescences in a large number of places and spreading from these over the surrounding country. Hence the primary importance of preventing these recrudescences: this is a matter of much difficulty due to the impossibility of discovering definitely every endemic centre, whilst they must be attacked before infection becomes active, which makes the time available for the operations very short. The work is then so enormous that plague will break out in many places before all, or even a number of, the endemic centres have been treated. The operations in 1906 have, however, been fairly successful in stamping out recrudescence or in causing comparative freedom from the disease. Evacuation was found to be the most effective measure; disinfection is not of so much advantage as it is but rarely that information is other young age groups of the population appears to have been excessive in Belfast. The causes operating to produce this relatively high mortality at these young ages should be thoroughly investigated.

6. The mean annual mortality from enteric fever has been so exceptional in Belfast for the last 25 years that it appears to have no parallel in any other city or large town in the United Kingdom. Insanitary conditions have no doubt played a very important part in fostering enteric fever in Belfast, but cannot of themselves account for so excessive a mortality from this disease or for other features of its history. The water-supply cannot account for fever in Belfast, because there has been no relation between the distribution of the disease and the distribution of any one of the three separate sources of water-supply. On the contrary, the incidence of fever on different parts of the city has been generally similar and simultaneous, irrespective of water-supply or insanitary conditions, and moreover it appears to have almost exclusively affected the working-class areas of the city. Neither can the constant excess of enteric fever in Belfast be attributed to the local and occasional outbreaks which have been traced to infected milk. On the other hand, the known features of the history of Belfast fever are consistent with an explanation attributing them to the influence, direct and indirect, of shell-fish gathered from the grossly contaminated foreshores of Belfast Lough.

7. No system of sewage treatment, within practicable limits of cost, will fully safeguard the lough shell-fish, and we are of opinion that powers should be obtained to prohibit the gathering of these shell-fish for human consumption.

8. Mortality referred to phthisis and other tuberculosis diseases has been, and is, excessive in Belfast in comparison with English and Scottish cities, but it has not been exceptional for an Irish city. Since 1895 there has been some diminution of it in Belfast. The age and sex incidence of phthisis mortality in Belfast and Ireland is very different from what it is in Manchester and in England and Wales. It may to some extent be due to differences in disease nomenclature in the two countries. The whole question of phthisis in Ireland seems to us to require further and exhaustive inquiry.

9. We have refrained from any recommendations in regard to the notification of phthisis and the provision of sanatoria or dispensaries, as the Local Government Board for Ireland have advised local authorities in recent circulars, and we understand that a Bill on these subjects is about to be introduced by the Chief Secretary for Ireland.

The report with its severe strictures and its numerous recommendations thoroughly justifies the action of the citizens and of the medical profession who, in the interests of their city and of public health, demanded the inquiry. We propose to discuss some of the features of the report in a future article.

SANITARY REFORM IN INDIA.

VII.[1]—THE ANNUAL SANITARY REPORTS.

THE annual reports of the authorities responsible for the sanitation of the various provinces of India for the year 1906 deal with an immense amount of material in connexion with Bengal, Eastern Bengal and Assam, the United Provinces, the Panjab, the Central Provinces and Berar, Burma, the North-West Frontier, Bombay, and Simla.

Bengal.

The thirty-ninth annual report of the Sanitary Commission for Bengal for 1906 is issued by Lieutenant-Colonel F. C. Clarkson, I.M.S., the Sanitary Commissioner for that province. It deals comprehensively with the facts relating to the meteorology of the year, the vital statistics, the history of the chief diseases and of vaccination, the sanitary works, and the work of the Sanitary Board. With respect to the meteorological facts, the rainfall was remarkably heavy during the cold season months; that of February established an absolute record, the number of rainy days being three or four times greater than usual; in contradistinction to this the monsoon period generally gave but a scanty rainfall with irregular distribution, and the public health was thereby affected and was worse in 17 districts. The vital statistics showed a falling off in both the number of births and deaths recorded, amounting to 116,268 in the case of the former and 114,439 in that of the latter. The reduced birth-rate was evidently due to the general unhealthiness of the year 1905 and to the prolonged continuance of high prices of food grains everywhere, which, by lowering the vitality of the people, acted as a check on the growth of the population. As regards the deaths, the decrease was due to the comparatively smaller mortality from plague and fever.

Coming next to the history of the chief diseases, we find that there were a much extended prevalence of, and a serious rise in the mortality from, cholera, there having been 192,596 deaths, as compared with 116,490 deaths the average mortality of the five years 1901–05, the respective ratios being 3·81 and 2·33 per 1000. In fact, never since 1900, when the cholera mortality was the highest ever recorded, has there been such a heavy loss of life from this cause. The mortality was highest in the province as a whole during April and May and lowest in February and January. The death-rate from small-pox was more than thrice as large as in the preceding year, the ratios being respectively 0·43 and 0·14 per 1000. With respect to plague there was a very satisfactory reduction, the total deaths being 59,619, against 126,084 in the preceding year, the ratios corresponding being 1·17 and 2·52 per 1000. A larger percentage of females perished than of males. During the year under report 1777 antiplague inoculations were performed, against 1544 during the preceding year. No cases of, or deaths from, plague were reported anywhere amongst the inoculated. The disease was most prevalent during the first four months of the year, there being then considerable coolness and excessive rains, whilst with the onset of the hot weather there was a sudden drop in the mortality. With regard to the means undertaken for its suppression chemical disinfection was carried out in special cases where it was asked for and in several municipal areas where it could be supervised. Disinfection by heat and examination of infected houses became very popular. At Barari a knapsack sprayer was used to spray the inside of infected houses with kerosene oil emulsion and was attended with signal success. Lastly, rat-killing is seen to be gradually becoming popular. In Jaghdispur this was carried on in a systematic way and the town enjoyed complete immunity from the disease, whilst the latter recrudesced and prevailed with much severity in adjoining thanas and nearly all the other towns in the district. Fever prevailed with somewhat less severity than in 1905, there being 1,126,315 and 1,214,487 deaths respectively. Antimalarial measures were carried on in certain districts, such as filling in hollows and depressions, clearing jungles, and spreading kerosene oil on all foul tanks and cesspools, and in one place quinine was distributed free as a prophylactic. Dysentery and diarrhœa caused 1809 more deaths than in 1905. The report concludes with the sections relative to sanitary works and the annual report of the Sanitary Board, Bengal, for 1906, together with the various appendices relating to the above facts.

Eastern Bengal and Assam.

Lieutenant-Colonel E. C. Hare, I.M.S., the Sanitary Commissioner for Eastern Bengal and Assam, furnishes the report for the year 1906 for this province. Here the district reports did not record any severe waves of cold or heat and the rainfall, evenly distributed over the land, was neither markedly excessive nor deficient. The high prices for grain and its scarcity, which had prevailed in 1905, continued also in 1906, but on investigation, although in some districts the scarcity was undoubtedly due to heavy and prolonged floods at the time when the rice crop was growing, elsewhere it seems to have been due rather to excessive exports of grain and to a limitation of the area under rice cultivation, owing to an increase in the demand for jute and the high price realised by its cultivation; but whatever were the causes of the scarcity, there is no evidence that the high price had any marked effect on the general health of the people, the provincial death-rate being approximately the same as it had been during the last five years and that from bowel complaints being only slightly in excess of the decennial rate. The provincial birth-rate was 37·38, as compared with the quinquennial rate of 39·63. The death-rate was 31·67 for the year, practically the same as that of the previous five years—viz., 31·66—and much lower than that for 1905, which was 35·06, this decrease being chiefly due to a lessened mortality from fevers. The chief causes of mortality were found to be fever, cholera, dysentery, diarrhœa, and small-pox. With respect to cholera the provincial death-rate was higher than that of the decennial average, although lower than that of 1905, the ratios being respectively 3·63, 2·45, and 4·77 per 1000. In the account of the causation we note the drinking of contaminated water as the immediate cause of the outbreaks, so much so that the people are at length beginning to realise the necessity of having good water and applications for grants for improving the existing tanks, making new ones, and sinking wells are numerous. Almost all the civil surgeons who have had to do with the epidemic outbreaks report very favourably on the preventive method of treating the water-supplies with permanganate of potassium.

With respect to the returns for fever, the rate was lower by 1·90 per 1000 than that of the last ten years, although it was high in certain individual towns and rural areas, such as the as motor traffic increases. It will be observed with satisfaction that the medical man was not held to have been to blame in any way for an accident which, as has been observed, might have been a very serious one for him. Medical practitioners in the exercise of their calling are likely at any time to find themselves urged to travel as rapidly as possible from point to point. Apart from the use of motor-cars, they have sometimes exposed themselves to censure for driving too fast, for using short cuts and bridle paths the dedication of which to public use has not been established, for riding their bicycles on footpaths, for trying to have public tramway cars stopped for their convenience at the nearest possible point to their patients' houses, and for asserting in other ways claims to privileges which they do not possess. All reasonable indulgence will no doubt be extended to any medical man hurrying to a patient's bedside when it is probably a case of "life or death" dependent upon his early arrival, but even this degree of urgency can confer upon him no right to imperil the lives or even the property of his fellow citizens, and the motor-car is so dangerous an engine when driven incautiously that nothing can justify departure from the rules that make for safety in using it. Mr. Corben, however, emerged with credit to himself and to his servant from a trial in which a counter-claim for heavier damages than he obtained for himself was made against him unsuccessfully, on the ground that his driver had been in the wrong.

THE NEW GALLERY.

THE twenty-first summer exhibition of the New Gallery was opened to the public on April 25th. The tendency of the exhibition is apparently year by year to devote a greater space to the arts and crafts—in the sense, that is to say, of jewellery, metal work, enamel, embroidery, and like applications of the handicrafts. Let us first consider the sculpture that is exhibited in the Central Hall, in which by far the most prominent piece in every respect is No. 307, "Adrift," by Mr. John Cassidy, a striking achievement in the nude which presents many features of anatomical excellence. The group is of a family adrift upon a raft and is composed of father, mother, and three children, a girl of about 15, a boy a year or two younger, and a male infant whom the mother clasps anxiously; the father stands up, waving a piece of sail to attract attention, and his commanding figure forms the apex of the group in a manner which suggests that upon him depend the fortunes of the family. A point upon which Mr. Cassidy is to be congratulated is that the mother and daughter are not merely two nude female figures of different sizes; that of the mother is the figure of a woman who has borne and nursed children, a point obvious to medical men, whilst the figure of the daughter, although the development of the breasts show her to have attained puberty, yet accurately presents the anatomy of a young girl. Another piece of sculpture which we can commend is No. 303, Mr. Conrad Dressler's bust of Sir William Crookes. No. 320, Messrs. Morris's tapestry, from a design by the late Sir E. Burne-Jones, is a noteworthy piece of work, both as to colour and execution, whilst Nos. 321 and 322, exhibits of jewellery by M. Lalique and M. Lucien Galliard, are well worth study. Of the pictures the most interesting to medical men is perhaps No. 242, the careful portrait of Mrs. Scharlieb, M.D., M.S., by Mr. Hugh Riviere. Another medical portrait, that of Dr. Alfred Wolff (No. 28), has been simply and effectively painted by Mr. Harold Speed. There are three portraits which stand out pre-eminent above the others, and we mention them in their order of excellence: First comes No. 239, Sir George Reid's dignified and strong presentment of Lord Halsbury. Next we should place No. 262, the Lady Constance Stewart of Mr. W. D. von Glehn, a portrait of incisive originality, and approaching to it, from the point of view of cleverness, is No. 125, a portrait of Miss Lewis by Mr. Sargent, a notable study in blues and greys. Other interesting portraits are Mr. Shannon's Mrs. Buckley (No. 226), Mr. Labery's Mrs. McEwen, Mr. George's Henry's Marchioness of Tullibardine (No. 218), and No. 145, Mr. John Collier's "Joan and Cyrus." With regard to the subject pictures, the two which will attract most attention are No. 223, "The Rajah's Birthday," by Mr. Frank Brangwyn, and No. 256, "Tom-tôm Players, Ceylon," by Mr. E. A. Hornell. They both handle broad effects of strong tropical light and shade in a masterly manner, and whatever may be thought of their respective merits there can be no doubt that Mr. Brangwyn's work affords the more daring conception of the two. As a contrast in effect, though equally striking in execution, is No. 120, "The Monastery," by Mr. S. Melton Fisher, a picture which shows the quality of imagination. In the balcony are exhibited numerous examples of handicraft and applied art, among which may be specially mentioned No. 325, silver work, by Miss Florence Steele, and No. 327, the silver and shagreen work of Mr. Paul Cooper. Various cases of jewellery are exhibited which are well-worth study; in one instance the artist appears to have derived inspiration from a careful study of the decorative features of the "valentine" of the mid-Victorian era.

WEST LONDON POST-GRADUATE COLLEGE.—The summer session will commence at the West London Hospital, where prospectus and syllabus of the course can be obtained from the Dean, on Monday, May 11th. The following arrangements have been made for the opening week:—Daily, 2 P.M., Medical and Surgical Clinics; X-Rays. 2.30 P.M., Operations. Monday and Thursday, 2 P.M., Mr. H. P. Dunn, Diseases of the Eyes. Tuesday and Friday, 10 A.M., Dr. J. A. M. Moullin, Gynæcological Operations; 2.15 P.M., Dr. H. J. Davis, Diseases of the Throat, Nose, and Ear; 2.30 P.M., Dr. P. S. Abraham, Diseases of the Skin. Wednesday and Saturday, 10 A.M., Dr. E. A. Saunders, Diseases of Children; 2 P.M., Dr. K. Scott, Diseases of the Eyes; 2.30 P.M., Dr. G. D. Robinson, Diseases of Women.

received sufficiently early to allow of its successful application. One of the best and most effective methods not only of mitigating plague incidence but also of diminishing its mortality when an epidemic is in progress was found to be inoculation. With regard to rat destruction, on account of the favourable results obtained it was pursued with vigour. Captain G. I. Davys, I.M.S., at Amritsur reports that out of 18 well-authenticated centres of endemic plague no case of plague occurred in 11 where rat destruction was thoroughly carried out. Amongst the other diseases noted we find that dysentery and diarrhœa accounted for a mortality of 0·87 per 1000, as against 0·68 in the previous year. The report concludes with an account of the sanitary work executed during the year, with some general remarks and with the usual statistics. We are glad to note here the free distribution of quinine by means of the vaccinators and other officials in the country districts.

MEDICINE AND THE LAW.

Jamaica Rum and Demerara Rum.

Messrs. J. H. Graham and Co., spirit merchants, were convicted recently at Newcastle and fined £5 with £20 costs at the instance of the Jamaica Government for selling a pint of spirit labelled "Jamaica rum" which was, in fact, rum from Demerara. The defendants pleaded guilty and excused themselves on the ground that little distinction was drawn in the north of England between Jamaica rum and the Demerara spirit and also that as only the price of the latter was charged the public was not defrauded. No doubt those interested in the trade of Jamaica instituted the prosecution with full cognisance of these facts and with the intention that the distinction between Jamaica rum and cheaper liquor of inferior quality should be brought to the attention of north country purchasers who can still buy Demerara rum under that title should they prefer it.

Exemplary Sentence on a Milk Dealer.

Considerable satisfaction must have been felt by those responsible for the recent conviction of a man named Joseph Winchester at Feltham who was charged with selling as milk machine-skimmed milk to which had been added, according to the analysis of two samples taken, 6 per cent. and 3 per cent. of water. He was charged with his brother George who when the inspector called his attention to the fact that the two cans from which he was asking for samples contained milk of different colour suggested that the cow in the case of one of them had been "fed on buttercups." There were no previous convictions against George Winchester, however, and his explanation that he was only acting for his brother Joseph, who was the owner of the business, contributed to his being punished by a fine of £1 only with costs. When, however, the bench came to deal with the case of Joseph the county inspector, Mr. Walter Tyler, laid before them a list of his previous convictions in various places since 1894 which had been punished by fines of 9*s.*, 6*d.*, £2, £1, £5, £9 3*s.*, £20, £25, and £100; the total, with costs, amounting to nearly £170. Attention may be called to the trivial penalties of 9*s.* and of 6*d.* inflicted on the first two convictions, which certainly did not act as a deterrent from what must have been a profitable form of fraud to a man who has now been sent to prison with hard labour for three months.

Death from Eating Chromate of Potassium.

An inquest was held recently at the City coroner's court upon a girl, aged 15 years, who had died as the result of eating a piece of chromate of potassium under the impression that it was a form of sweatmeat. Dr. F. J. Waldo in commenting on the fact that chromate of potassium is not subject to regulation as a scheduled poison, contrasted the ease with which a child might purchase it with the precautions which would surround the sale of a pint of beer to the same young person. There are, no doubt, some chemical substances which would be less likely to do injury to children or ignorant adults if they were always sold retail under labels showing them to be poisonous or even unwholesome. Children especially are not so wary as their seniors of trying experiments with anything that may turn out to be palatable, and photography, electricity, and other scientific mysteries of their parents' childhood supply the common plaything of the child of to-day. Young people, moreover (and even their elders), although they may have some knowledge of the substances which they are handling, may yet be careless in the matter of leaving them about, and may be rendered less so if they are reminded of their qualities.

Mr. Troutbeck on Deaths under Anæsthetics.

At a recent inquest at Westminster it was proved that the deceased, a boy, aged 13 years, had died while undergoing an operation under an anæsthetic in the Hospital for Diseases of the Throat, Golden-square, and the jury, after returning a verdict of "Accidental death," added the expression of their opinion that proper care had been taken by the authorities of the hospital. We have no doubt that this opinion was perfectly correct and those responsible for the administration of the anæsthetic in the case in question were without blame for the death into which the jury were summoned to inquire. We certainly, however, should not have regarded the opinion of such a tribunal as in any way conclusive had it been adverse and we do not concur in observations made to the jury by the coroner, Mr. John Troutbeck, upon the subject. He is reported to have referred to the very important subject of the administration of anæsthetics and of the deaths which take place under them and to have told the jury, no doubt correctly, that it was their function to satisfy themselves as to whether the cases inquired into were treated by persons possessing the requisite amount of skill and whether death occurred in spite of the due exercise of that skill. He then pointed out that the principal evidence on such occasions was that of the persons into whose conduct inquiry was being held (i.e., the medical men respectively administering the anæsthetic and performing the operation) and referred to post-mortem examination conducted by an independent witness, not connected with any hospital or with its medical staff, as the only check that could be had upon the conduct and evidence of the medical witnesses directly connected with the case. He admitted that the evidence of the latter was the more strictly valuable and that consequently the check was not a very effective one. With the opinion thus expressed, if we have summarised it correctly, we do not agree. The post-mortem examination held in such cases as those described will prove, or will corroborate other evidence with regard to, the physical conditions which led to the death of the patient. It cannot prove what was the conduct of the anæsthetist or of the surgeon during the period preceding the death apart from, or in contradiction of, their evidence, unless we assume that evidence to have been deliberately perjured and clumsily invented. They must remain the only witnesses as to what their acts or omissions may have been, and as members of an honourable profession they will give that evidence truly, even though in conceivable cases it may tend to convict them of error. The hardship to which they have to submit is that they must appear as witnesses before a jury of laymen who in the majority of cases are not even well-educated laymen.

A Medical Man's Motor-car in Collision.

An action in the Chepstow county court recently ended in a verdict for the plaintiff, Mr. C. Corben, for £16 in respect of damage done to his motor-car by another owned by Mr. R. G. Harding, and it would appear to be a matter of congratulation for the plaintiff that the injuries were inflicted upon his car only and were not of a more serious and personal character. The evidence showed that he was being driven to a patient's house and that as his car was issuing at a pace of between four and five miles an hour from a narrow side lane into a main road his driver sounded his horn, but that at the same moment the defendant's car, proceeding to the railway station to meet a train, for which purpose it was late, was coming along the middle of the road and was being driven at between eight and 12 miles an hour, in itself not an excessive rate of speed. The proof as to which car ran into the other, so far as it was independent of the evidence of eye witnesses, was established by the marks on the plaintiff's car, and the considerable damage done to that of the defendant was shown to have accrued after the impact when it became unmanageable and ran into walls, first on the one side of the road and then on the other. That this should have occurred at the point of collision shows that it was a place calling for the exercise of great caution and it is therefore not surprising that the dearth of signposts in Monmouthshire was commented upon unfavourably in the course of the case. Their effect in calling attention to "blind" corners round which vehicles may emerge unexpectedly is one which deserves the special attention of all local authorities of scarlet fever showed a further slight decline, but caused death-rates equal to 1·2 in Leyton and to 1·5 in Wallasey. The 35 deaths attributed to diarrhœa exceeded those in the previous week by five, and the 21 deaths referred to "fever" also showed a slight increase; the deaths from "fever" included three in Birmingham and three in Huddersfield. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily declined in the 20 preceding weeks from 5581 to 2887, had further fallen to 2861 on April 25th; 332 new cases were, however, admitted to these hospitals during the week under notice, against 297 and 328 in the two preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 274 in each of the two preceding weeks, rose to 301 in the week under notice, and corresponded with the corrected average number in the corresponding week of the five years 1903–07. The 31 deaths directly referred to influenza in London showed a further decline from the numbers in recent weeks. The causes of 62, or 1·3 per cent., of the deaths registered in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 47 other smaller towns; 12 uncertified causes of death were, however, registered in Birmingham, nine in Liverpool, eight in Gateshead, and seven in Sheffield during the week under notice.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 19·7, 18·8, and 16·4 per 1000 in the three preceding weeks, rose again to 18·8 in the week ending April 25th, and exceeded by 3·4 the mean rate during the same week in the 76 large English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 11·4 and 12·3 in Aberdeen and Leith, to 20·7 in Perth and 21·4 in Paisley. The 663 deaths in these eight towns showed an increase of 85 upon the number returned in the previous week, and included 77 which were referred to the principal epidemic diseases, corresponding with the number in the previous week; of these, 34 resulted from measles, 14 from diarrhœa, 12 from whooping-cough, seven from "fever," seven from diphtheria, and three from scarlet fever, but not one from small-pox. These 77 deaths were equal to an annual rate of 2·2 per 1000, while the mean rate from the same diseases in the 76 English towns during the week did not exceed 1·2. The 34 fatal cases of measles showed a further decline from the numbers in recent weeks, and included 25 in Glasgow, seven in Edinburgh, and two in Paisley. The 14 deaths attributed to diarrhœa exceeded the number in the previous week by three. The 12 fatal cases of whooping-cough were, however, fewer than in any recent week; four occurred both in Glasgow and in Edinburgh and two in Dundee. The seven deaths referred to "fever" were all returned in Glasgow; of these, five were certified as cerebro-spinal meningitis and two as enteric. Of the seven fatal cases of diphtheria three occurred in Glasgow and two in Dundee; and all the three deaths from scarlet fever were returned in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 128 and 121 in the two preceding weeks, further declined to 113 in the week under notice, but exceeded by one the number returned in the corresponding week of last year. The causes of 24, or 3·6 per cent., of the deaths in these eight towns during the week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death in the same week did not exceed 1·3 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 22·5 and 23·1 per 1000 in the two preceding weeks, declined to 21·1 in the week ending April 25th. During the first four weeks of the current quarter the death-rate in Dublin averaged 23·2 per 1000; the mean rate during the same period did not exceed 15·4 in London and 15·6 in Edinburgh. The 160 deaths of Dublin residents registered in the week under notice showed a decline of 15 from the number returned in the previous week, and included seven which were referred to the principal epidemic diseases, corresponding with the number in the previous week. These seven deaths were equal to an annual rate of 0·9 per 1000, the rate during the week from the same diseases being 1·3 in London and 1·9 in Edinburgh. Of these seven deaths from epidemic diseases in Dublin three resulted from measles, two from whooping-cough, and two from diarrhœa, but not one either from scarlet fever, diphtheria, "fever," or small-pox. The fatal cases of measles corresponded with the number in the previous week, while those of whooping-cough were fewer by one. The 160 deaths from all causes in the city during the week included 26 of infants under one year of age and 43 of persons aged upwards of 60 years; the number of deaths of elderly persons showed a considerable decline from the numbers in recent weeks. Two inquest cases and two deaths from violence were registered, and 82, or 51·3 per cent., of the deaths occurred in public institutions. The causes of seven, or 4·4 per cent., of the deaths registered in the city during the week under notice were not certified; all but one of the 1420 deaths in London last week were duly certified, and in Edinburgh the proportion of uncertified deaths did not exceed 1·6 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: C. Bradley to the *Cæsar*, on recommissioning; J. L. Smith, M.V.O., to the *President*, additional, for three months' course at West London Hospital; H. B. Beatty to Royal Marine Division, Chatham; and R. Miller to the *Magnificent*. Staff-Surgeons: S. Roach to the *President*, additional, for three months' course at West London Hospital; N. J. Roche to the *Victory*, additional, for Portsmouth Dockyard; W. K. Hopkins to the *Edgar*, temporary; E. G. E. O'Leary to the *Sutlej*, on recommissioning; and E. S. Miller to the *Cornwallis*, on recommissioning. Surgeons: G. E. Hamilton to the *Hannibal;* W. N. Blatchford to the *Sutlej*, on recommissioning; C. K. Bushe to the *Cornwallis*, on recommissioning; P. D. Ramsay to the *Vivid;* and W. T. Haydon to the *Vivid*, additional, and to the *Cæsar*, on recommissioning.

INDIAN MEDICAL SERVICE.

The King has approved of the following retirements:—Lieutenant-Colonel Alfred Ernest Roberts (dated April 21st, 1908). Lieutenant-Colonel William Alexander Lee (dated April 7th, 1908). Lieutenant-Colonel Kavasji Hormasje Mistri (dated March 4th, 1908).

VOLUNTEER CORPS.

Rifle: 3rd (Duke of Connaught's Own) Volunteer Battalion, The Hampshire Regiment: Surgeon-Captain Bonner H. Mumby to be Surgeon-Major (dated March 17th, 1908); Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Charles Knott resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 20th, 1908). 5th (Isle of Wight, Princess Beatrice's) Volunteer Battalion, The Hampshire Regiment: James Albert Gibson to be Surgeon-Lieutenant (dated March 1st, 1908). 2nd Volunteer Battalion, The Essex Regiment: Kenneth Simonds Storrs to be Surgeon-Lieutenant (dated March 6th, 1908).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Bedford Bearer Company: Supernumerary Captain Edmund F. Bindloss (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, Bedford Volunteer Infantry Brigade) to be Major, remaining supernumerary (dated Feb. 1st, 1908).

ROYAL ARMY MEDICAL CORPS AMBULANCE SECTION.

Permission has been given for the formation of an Ambulance Section of the Royal Army Medical Corps at Camborne and Redruth in connexion with the Plymouth Field Ambulance, R.A.M.C. The head-quarters will be at Camborne.

LITERARY INTELLIGENCE.—Messrs. Cassell and Co. are issuing almost immediately a new and revised edition of "Hygiene and Public Health," by Dr. B. Arthur Whitelegge and Dr. George Newman. The same publishers are also producing a new volume by Dr. G. Ernest Herman, entitled "The Student's Handbook of Gynæcology," based upon the author's "Diseases of Women." It contains 172 illustrations.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 1st, 1830.

ON THE MEDICAL SERVICE OF THE EAST INDIA COMPANY.

LETTER IV.[1]

To the Editor of THE LANCET.

SIR,—Before proceeding further in the consideration of the ultimate and sole recompense to medical officers of the East India Company's service, that is, their retiring pensions, it may be proper to mention the form of admission, at the India House, of recruits for this establishment, which is well calculated to deceive. It is this; that "assistant surgeons are permitted to proceed to their respective presidencies, Calcutta, Madras, or Bombay, as the case may be, to practise as *surgeons, and to be admitted on the* establishments as vacancies may occur." This form has been observed for the last ten or twelve years. To practise as *surgeons, where?—Upon whom?—For what?* —The thing is quite absurd, and ridiculous; and merely "ad captandum"—to deceive, by giving an idea that, independent of the high prospects which the Company's service holds out, money is to be made in India, even on landing, by private practice! It is but fair, however, to mention, that, according to the present writer's information, no one has hitherto been left to absolute starvation in this way. Medical officers, shipped for India, in compliance with requisitions to the Court of Directors from the several presidencies, *have hitherto been wanted to fill up vacancies,* occasioned by casualties, long before the period of their arrival in India. At the presidencies, medical practice is in the *hands of two or three Company's surgeons. It is only at the* Presidencies, that medical officers are paid for professional attendance. At out-stations, a "honorarium," or fee, to the medical attendant, is seldom, if ever, dreamt of; so that, on the Madras establishment, at least, not above one surgeon in one hundred, after from twenty to thirty years' service, happens to receive, in fees and presents, a sum equal to the *payment of his passage-money back to England*, or 2,000 rupees. Medical men are not prohibited from receiving presents, or fees, in India, on account of professional practice; but their *patients (excepting at the Presidencies,* or towns of Calcutta, Madras, or Bombay) must necessarily be Company's servants; and it is not obligatory on them to pay for medical *advice and attendance*; whereas, the attendance of medical men, on all occasions, is obligatory, with or without a fee. Medical men never expect, it may *be said never accept*, a *remuneration from the military*; and civilians, who alone are able to pay them, very seldom think any return for their assistance necessary. It has been ruled, *however, by the supreme government*, and by the subordinate governments, that it is the duty of every medical man, to attend at the call of any person within his reach who *may* want his *services*, without fee or reward, and at his own expense for personal conveyance. Let it be understood that such unrequited summonses are often frivolous, and at distances of *upwards of* fifty miles. Disobedience of these calls renders the surgeon liable to trial by court-martial; or to suffer by the more usual mode of punishing medical delinquents—marching them incessantly about the country to the most distant places, until they sink under fatigue, privation of every sort, despondency, and the malignant influence of the climate. *From* natives, who seldom ask the help of an English surgeon, the compliment seldom exceeds a small present of fruit, or sweetmeats, a fowl, or a lean goat, or sheep, and, on very extraordinary occasions, perhaps, a well-darned shawl, not worth 20 rupees, and which has been an heir-loom in the family for the best part of a century. So much *for the practice* of a surgeon in India. ......

Let us now see, by a comparative statement, in what proportions the Honourable Company *compensate* and appreciate the labours of their two classes of servants—*soul*-curers and *body*-curers.

Pay on Retirement.

"A chaplain, after eighteen years' service in India, including three years for one furlough," (that is, after fifteen years' actual residence in India), "*is* allowed to retire on the pay of lieutenant-colonel, 365*l.* per annum."

"A medical officer, after twenty years in India, including three years for *one* furlough," *(that is, after seventeen years'* service in India,) "is permitted to retire from the service on the pay of captain, 191*l.* 12*s.* a year." After twenty and *thirty years' service in India*, the same, *191l. 12s.*

"A chaplain, if *compelled to quit the service on account* of ill health, after ten years' service in India, is allowed to retire on the half-pay of lieutenant-colonel, 200*l.* 15*s.* a year.

"A *medical officer, if compelled to* quit the service on account of ill health, *after ten years' service in India,* is (or rather was) permitted to retire on the half pay of lieutenant, *73l.*; *after* six years, on the half pay of ensign, *54l. 15s.*; after thirteen, on the half pay of his rank, that of full surgeon, if fortunate, 127*l.* 15*s.*; or of lieutenant, if the reverse, *73l.*

"A chaplain, after seven years' residence in India, is allowed to come home on furlough, and receive the pay of *major*, *292l.* a *year; should he come home from sickness* prior to this period, he is to receive the pay of captain only."

"A medical officer, after ten years' service in India, is allowed *to come home* on furlough, and *receive the pay of* lieutenant, 95*l.* 16*s.* 3*d.* a year."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8013 births and 4780 *deaths were registered during the week ending* April 25th. The annual rate of mortality in these towns, which had steadily declined in the four preceding weeks from 17·4 to 15·2 per *1000*, was equal to *15·4 in the* week under notice. During the first four weeks of the current quarter the death-rate in these towns has averaged only 15·7 per *1000*; the rate in London during the same period did not exceed 15·4. The lowest annual death-rates in the 76 towns during the week under notice were 6·7 in Hornsey, 7·3 in Willesden, 8·1 in Southampton, and 9·3 in King's Norton; the rates in the other towns ranged upwards to 20·5 in Devonport, 20·9 in Oldham, 22·9 in Rochdale, and 23·5 in Stockton-on-Tees. The rate of mortality in London during the week did not exceed 15·4. The 4780 deaths in the 76 towns during the week showed an increase of 32 upon the low number returned in the previous week, and included 376 which were referred to the principal epidemic diseases, against numbers declining from 487 to 382 in the four preceding weeks; of these, 138 *resulted from whooping-cough*, 101 from measles, 49 from diphtheria, 35 from diarrhœa, 32 from scarlet fever, and 21 from "fever" (principally enteric), but not *one from* small-pox. The deaths *from* these epidemic *diseases* were equal to an annual rate of 1·2 per 1000, *corresponding with the rate in the previous week; the rate* from the *same* diseases in London *was equal to 1·3*. No death from any of these epidemic diseases was registered last week in Leicester, York, Aston *Manor, Coventry, or in* nine other *smaller towns;* the annual death-rates from these diseases, however, ranged upwards to 2·8 in Huddersfield, 3·0 in Smethwick and *in Birkenhead*, and 3·5 in Rochdale. The fatal cases of whooping-cough in the 76 towns, which had been 204, 150, and 134 in the three preceding weeks, rose again to 138 *in the week under notice*; the highest death-rates from this disease in these towns last week were 2·0 in Sunderland and in Newport, 2·3 in Smethwick, and 2·6 in *Devonport*. The 101 deaths from measles were fewer by 26 than those in the previous week; they caused death-rates, however, equal to 1·1 in Salford and in Swansea, 1·3 in Birkenhead, and 1·8 both in Preston and in Rochdale. The deaths from diphtheria, which had been 53 and 39 in the two previous weeks, rose again to 49 last week, and included 13 in London, four in West and East Ham, two in Wolverhampton and in Walsall, four in Liverpool, *five in Manchester and Salford,* three in *Hull, and two in* Middlesbrough. The 32 fatal cases

Sambon says the disease is known as croup or angina in full-grown animals but in calves is known as diphtheria. Now we are on safe ground and we may take the calves as exhibiting "diphtheria." The term croup or angina signifies to me nothing but a sore-throat, it is a clinical term, certainly not diphtheria as we know it in man. *Diphtheria in calves has nothing whatever to do with diphtheria in man.* The cause of calf diphtheria is well known and inquiry would have informed Dr. Sambon that it is due to the bacillus of necrosis and not to the Klebs-Löffler organism. This was shown by Löffler long ago—by one of the discoverers of the organism said to produce human diphtheria—and yet despite this fact, Dr. Sambon says calves suffer from (human) diphtheria or a diphtheritic condition transmissible to man. The most interesting case of diphtheria in the cow he does not refer to, that described by Dean and Todd in the *Journal of Hygiene*. In this case there was no doubt but that the disease had been inoculated into the cow by the milker and in all cases of diphtheria in the cow with which I am acquainted the animal suffered as a consequence of infection from a human source or from experimental inoculation. The cow was the unhappy victim, but because of her misfortune the disease cannot be assigned to the cow as an infection natural or common to the cow. Dr. Sambon in his paper brings in a lot of extraneous matter, including tuberculosis. I may be permitted also here to refer to that infection. Tuberculosis is extremely rare, if ever it occurs, as a natural infection of rabbits and guinea-pigs. These animals may, however, be readily infected, and so it may happen with the cow in diphtheria. I think I am justified in saying that any cow showing lesions containing the organism of human diphtheria has been infected from a human source. So far as I am aware there is no recorded case of diphtheria in the cow where the human element can be entirely excluded. Dr. Sambon says as to sheep, "The disease is especially prevalent in young lambs; it is in every way similar to that of calves." *This is perfectly true; the cause is the same:* the bacillus of necrosis. I am not prepared to say that swine may not be infected because they are open to infection probably more than any other of the domestic animals that do not cohabit with man. The reason is obvious because of the material often given to swine. I can imagine a pig becoming infected that has been fed on poultices used upon human diphtheritics and other material coming from the sick room, but nevertheless an undoubted case of diphtheria in swine has to be recorded. Lesions occur in this animal also due to the bacillus of necrosis. As to the rabbit, the organism just mentioned is peculiarly fatal for this animal, and judging from the lesions met with in rabbits I am surprised that these animals have not been claimed by Dr. Sambon as subject to diphtheria. I am inclined to some extent to agree that the cat may be the means of disseminating the disease, but I consider in this case that we may look upon the animal as a literal intermediary bearer—a mere transmitting agent of the disease. The animal is infected from a human source and conveys it to other human beings. It may suffer from the disease or it may convey infective material from patient to healthy subject in its fur. The cases in cats can all be traced originally to a human source and although this is the case diphtheria as a disease in cats and dogs is rare. I place no weight whatsoever upon the reference given to the disease in dogs mentioned by Williams as having been seen in the winter of 1878–79. If diphtheria was even rarely met with we should have heard of cases recorded by the many eminent veterinarians who have made the diseases of dogs their earnest and continuous study.

Now as to the disease in birds. Avian diphtheria is not due to the Klebs-Löffler organism. I agree with Ritter that organisms indistinguishable from the organism of necrosis in calves may be abundantly met with and I have experimental proof of fowls being infected directly from calves suffering from so-called calf-diphtheria. In widespread epidemics among pigeons the cause is doubtless other than the organism of necrosis, and Leclainche has shown that in an epidemic he investigated the cause was an organism included in the group of organisms producing septicæmia. Various opinions are held as to the cause of avian diphtheria, which I need not trouble your readers with, not the least interesting organism being a protozoon. Certain it is that those who have worked at this disease in birds are not unanimous as to the organism, but the Klebs-Löffler bacillus is not claimed as the causal agent. I think, therefore, that Dr. Sambon will have to produce more evidence than he has done in support of his opinion that the organism of human diphtheria attacks the lower animals to the degree he maintains. It cannot be placed to the ignorance of members of the veterinary profession that they have hitherto failed to diagnose lesions produced by this organism because clinical evidence has been wanting, and I am certain I am now voicing the whole of the profession. If ever a case had arisen where there was reason to suspect diphtheria they would not have failed to send the material where a correct diagnosis could be made. At any rate, no one has the right to say that such material exists and that the profession has failed to recognise it and that we require the assistance of others to make our diagnosis. We of the veterinary profession pay particular attention to the diseases transmissible from animals to man, and if diphtheria were at all common, or even if it were a comparatively rare event, then there would be no hesitation in making the facts known; indeed, it would be our bounden duty so to do. I am afraid, at the risk of being told to mind my own business, I must say there is too great a tendency to blame the cow (and other animals) for the spread of epidemics and that every avenue for the propagation of the disease is not closed before the cow is called in and summarily convicted. Anyone familiar with our milk-supply, to give a single instance, and the way that very necessary commodity is treated in its course from cow to consumer need not marvel that it is a vehicle for spreading disease. The *fons et origo* is not in every case the cow, and to do her justice we have no right to modernise *cherchez la femme* into *cherchez la vache*.

I am, Sir, yours faithfully,
A. E. METTAM.

Royal Veterinary College, Dublin, April 20th, 1908.

INFANT INSURANCE.

To the Editor of THE LANCET.

SIR,—It is most sincerely to be hoped that the "Children's Bill," which contains so many useful provisions for preserving and improving child life, will not be allowed to suffer in the "massacre of the innocents" with a view to lighten this session's somewhat crowded programme. There is, moreover, one direction at least in which it seems most desirable that the Bill should be extended, inasmuch as it does not at present deal in any way with the existing system of infant insurance. The constant decline in the birth-rate affords undeniable evidence of decreasing appreciation of the value of children in the family circle. This accentuates the undesirability of permitting the insurance of infants whose parents are unable to prove an insurable interest in their lives. Infant insurance is practically universal among the wage-earning classes, fostered as it is by the large army of agents employed by rival industrial insurance companies; and having regard to the acknowledged waste of infant life owing to ignorance and neglect, it seems impossible to defend a system which provides payment of sums varying up to £6 on the death of a probably sickly infant which at the same time relieves the parents of the trouble and expense of the child's upbringing. The insurance of infants, except by their parents, is not permitted by the rules of most industrial insurance offices, but there is abundant evidence that these rules are not strictly observed. Mr. Robert J. Parr, director of the National Society for the Prevention of Cruelty to Children, when under examination by the committee appointed to consider the advisability of extending the provisions of the Infant Life Protection Act to one-child cases, gave evidence as to the well-known fact that baby-farmers very frequently succeed in insuring the lives of the infants committed to their charge. It is not necessary to suggest that any infants are deliberately "done to death" for the sake of insurance money in order to condemn the system of the insurance of infants as not being conducive to the increased personal care and attention necessary for the reduction of the present excess of infant mortality. The principal industrial insurance offices instruct their agents not to accept a proposal to insure an infant under the age of 14 days, and further that illegitimate children are not to be insured until they have attained the age of three years. Neither of these instructions is, however, strictly observed by insurance agents, since infants are constantly insured as soon as they are born, and insurances are very frequently effected and paid on the deaths of illegitimate children under three years of age. There is, on the whole, abundant ground for urgently desiring that a clause should be added to the "Children's Bill" in Committee restricting or prohibiting the insurance of any infant

Correspondence.

"Audi alteram partem."

THE EPIDEMIOLOGY OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—Dr. L. W. Sambon's article on "The Epidemiology of Diphtheria in the Light of a possible Relationship between the Diphtheritic Affections of Man and those of the Lower Animals," which appeared in THE LANCET of April 18th, p. 1143, will not, I hope, be regarded as one of mere academic interest. To neglect to inquire into the truth or otherwise of his statements could only be regarded as a criminal disregard of warnings based upon facts put forward with a convincing accuracy and acumen that nothing but close scientific investigation can substantiate or refute. We are becoming so accustomed to hear of, and to be shown, the close inter-relationship between, and the intermutability of, diseases of men and animals that Dr. Sambon's contention comes as no surprise to us. Because there is no direct proof that diphtheria in the pigeon and other animals causes disease in man we are not justified in throwing the subject aside. Inductive and deductive arguments since the more materialistic forms of acquiring knowledge—viz., bacteriology, chemistry, and the microscope—came into more general use are apt to be slighted. We are inclined to judge at the present day by our senses only, whilst our reasoning is granted but little favour. Of course, there are theorists and theorists, but Dr. Sambon's theory, if so practical and convincing an argument as he presents can be styled a mere theory, is no fiction but a grouping of facts and an exposition of conclusions based on these facts arranged in logical sequence which must either be refuted or acted upon. There is no intermediate position and, as his facts are irrefutable, the brunt of the consequence likely to ensue by the neglect of these facts lies with those in authority who fail to act upon the evidence. The transmutability of diphtheria to men from animals has long been suspected and Dr. Sambon has shown how the epidemiology of diphtheria, which has hitherto been so obscure, may be explained. The fowl and the egg are incriminated in the process and it is interesting to note that the eastern counties of England where diphtheria in man is most common are the chief poultry-raising districts of Britain. It is to these counties, moreover, that the migratory pigeons mostly come. An interesting and original suggestion is the part played by eggs in the transmission of disease. I have myself noticed "blemishes" in the white of many eggs, mostly pink patches of delicate membrane, which I was wont to regard as signs of commencing embryonism. Recently, however, Professor Blanchard has shown that these patches contain a nematode worm (*Heterakis papillosa*). The explanation carries but little comfort to us, as we have hitherto regarded fresh eggs as being a food impossible of contamination by infection. Poultry and eggs as articles of diet require therefore to be inspected as carefully as beef, mutton, pork, and fish, and the proper place at which the inspection should be carried out is not in the market-place or shop but in the district in which the fowls are bred and reared. The fowl-house and the eggs must, if we are to act rationally, be legislated for as carefully as in the case of the cow and the milk when dealing with tuberculosis prophylaxis. Our supplies of fowls and eggs are largely derived from the south of Russia and from many districts around the Mediterranean, especially the north African shores. These supplies we cannot control hygienically but we can, and ought to, see that the sources of supply in Britain are wholesome and free from disease. It would be a great advantage commercially were our home poultry industry guaranteed to be sound, and it should be the endeavour of poultry farmers from a monetary point of view alone, leaving the health of the people out of the question, to have their farms placed under official inspection. The answer to this note of alarm is that fowls and eggs are cooked before being eaten and, therefore, there is no need for alarm. Assuming that all eggs are cooked before being consumed, which, of course, is not the case, we have still the fowl to deal with, and from the fowl other animals and man may be directly infected by one of the most terrible of our maladies. An inquiry is imperative if only to allay alarm; but from the immense number of facts recorded not only by Dr. Sambon but by many observers in several countries, it would only be in accordance with the proved relationship of the intermutability of other diseases between men and animals were it positively shown that the *phasianidæ* are the hosts of the diphtheritic poison which they not infrequently communicate to man. I am, Sir, yours faithfully,

London, April 27th, 1908. JAMES CANTLIE.

To the Editor of THE LANCET.

SIR,—I have read Dr. L. W. Sambon's communication in THE LANCET of April 18th, p. 1143, on the Epidemiology of Diphtheria with much interest and taking advantage of the quotation which heads your correspondence column I venture to offer a few remarks. Dr. Sambon says, "In an inquiry of this kind I should like to see the veterinary surgeon of the modern school take his full share of research work rather than adopt, as in the past, a negative hostile attitude which would be ridiculous in the face of the scanty and crude information at present available on the diphtheritic affections of animals." This, after an attempt to show that diphtheria is a disease of the lower animals, sounds as if the veterinary profession had studiously ignored the presence of diphtheria in the lower animals, although to Dr. Sambon the disease is so rampant that it is actually calling out to be diagnosed. In his efforts to show that diphtheria is common in the lower animals he quotes not only from a comedy of Plautus but even also from Numbers and it would appear that he would have the veterinary profession take its bacteriology and pathology from these sources. Because pigs suffered and died from very sore throats, according to Plautus, and the Israelites took quail that disagreed with them we are to believe that diphtheria existed in the lower animals. How easy it is to work up the history of disease when we see references which may have some bearing upon the subject and require only a little stretch of imagination to make them tally exactly with our preconceived notions. The historical references and most of Dr. Sambon's quotations will not bear inspection for a moment.

Before pointing out some of the errors in the article referred to I should like to inform Dr. Sambon that by diphtheria I understand an infection due to the ravages of the Klebs-Löffler bacillus, an organism that not infrequently leads a saprophytic existence and may be observed in the perfectly normal human fauces. The term diphtheria has unfortunately been used for conditions observed in the lower animals which are due to causes other than the Klebs-Löffler bacillus. Indeed, I think I am correct when I say that the cases observed in the lower animals directly traceable to the Klebs-Löffler bacillus may be counted on the fingers of one hand, and in these cases there is grave reason to believe that they were related to direct infection from a human source. Of course, I shall be at once consigned to the old school of veterinarians by Dr. Sambon for such an opinion, but then those of us who spend our days making post-mortem examinations and working with the pathological material obtained from the lower animals can only preach the faith that is in us and take facts as we find them. I quite agree with the opinion expressed by Friedberger and Fröhner (which Dr. Sambon quotes) relating to the transmission of diphtheria from animals to man—i.e., animal diphtheria is "a mere assumption due to ignorance of veterinary pathology." Let us examine the evidence the writer has brought forward in support of his contention that the lower animals do suffer from unrecognised diphtheria. The only evidence that is worth consideration is that given by men who are in a position to give an opinion. What Noah Webster thought in 1800 and what many of the writers of reports to the Local Government Board of later date believe may be dismissed in a word. Their opinions are framed on hearsay evidence or on incomplete clinical records. In many cases the conclusions savour of the *post hoc, ergo propter hoc.*

Dr. Sambon says diphtheria is known to occur in the horse. The only case which needs reference is that of Dr. Louis Cobbett where was found in the nasal discharge the Klebs-Löffler bacillus. This does not prove, however, that the horse was suffering from diphtheria despite the fact that the daughter of the owner had diphtheria and it would have been interesting to learn what condition was found on post mortem if the animal died. I do not think we need be surprised to find the Klebs-Löffler organism in the discharges from the horse's head, nor can we claim that its presence signifies in this case diphtheria because the organism may be found in throats free from any lesion whatsoever. In this case the lesions observed would be more valuable than the discovery of a particular organism. Then in cattle Dr.

The anæsthetics up to quite recent years were invariably given by the dressers in the eye wards, none of whom had much previous experience; indeed, many of them gave an anæsthetic for the first time under my supervision. *Out of the whole number there was but one death, that of a patient suffering from exophthalmic goitre.* The anæsthetics chiefly used were in the early years bichloride of methylene and chloroform, but occasionally a new one was given a trial. Later A.C.E. mixture became the mainstay in the eye wards and continued to be up to the end of my time. My experience seems to show that deaths from anæsthetics *per se* are extremely rare and that those which, according to the coroners, are so frequent are due to other causes, and the less said about them in this connexion the better, especially if, as Dr. Silk says, the reports get into the lay press. In the interests of the public, who are already quite nervous enough about anæsthesia, the coroners, who can have no practical experience of the administration of anæsthetics, would do well to lay to heart two old proverbs: (1) That the cobbler should stick to his last; (2) That to speak is silver but silence is gold.—I am, Sir, yours faithfully,

CHARLES HIGGENS, F.R.C.S. Eng.
Consulting Ophthalmic Surgeon to Guy's Hospital.
Brook-street, W., April 10th, 1908.

To the Editor of THE LANCET.

SIR,—A letter appeared from Mr. Coroner F. J. Waldo of London in the Dublin *Evening Mail* of about 14 days ago in which he commented on the very few fatalities from chloroform which were reported from Ireland as compared with London. A somewhat similar state of affairs prevails with regard to Scotland, but Dr. Waldo suggests as an explanation that either Dublin hospital surgeons do not report chloroform fatalities or the Dublin coroner refuses to hold inquests thereon. As this theory implies a grave imputation it is right to say that as a member of the corporation inspection committee of the Dublin hospitals such a complaint has never been made to us regarding any of the surgeons, and such a complaint concerning the coroner has never been made to the Public Health Committee whilst I have been a member of it. It is fairly certain then that Dr. Waldo's conjecture is baseless as regards Dublin.

I am, Sir, yours faithfully,
J. C. MCWALTER, M.A. R.U.I., M.D. Brux.,
Dublin, April 25th, 1908. F.F.P. & S. Glasg.

WORTH'S ADVANCEMENT OPERATION.

To the Editor of THE LANCET.

SIR,—In a notice of Colonel Maynard's excellent book on "Ophthalmic Operations" in THE LANCET of April 25th, p. 1216, the reviewer expresses the opinion that my advancement operation is "founded upon a fallacy and practical experience shows that it possesses notable disadvantages." Whose "practical experience"? I think that I may claim to have performed more advancement operations than most ophthalmic surgeons and I have used this operation exclusively during the last dozen years. I know from published accounts and private correspondence that this operation is used habitually by many of the most skilful operators both in this country and abroad. Its advantages are many. Its one disadvantage is that the stitches are not quite so easily removed as in some other operations. I do not for a moment suggest that your reviewer was actuated by personal motives when he went out of his way to make this remarkable statement. But I do respectfully suggest that such a statement should not have been made anonymously or without giving reasons.

I am, Sir, yours faithfully,
Harley-street, W., April 27th, 1908. CLAUD WORTH.

THE INHALATION TREATMENT OF CONSUMPTION AND "CATARRH."

To the Editor of THE LANCET.

SIR,—I have read with great interest Dr. Ash's remarks that appeared in THE LANCET of April 25th, p. 1236, on the inhalation treatment of consumption. For many years I have advocated the inhalation method as an important aid in the treatment of pulmonary and laryngeal tuberculosis. It is quite true that the inhalation of volatile substances produced by the ordinary respirators, mouth inhalers, and sprays is not satisfactory, as it cannot reach far enough down the lungs to be of any real service in the arrest of consumption. Two conditions are necessary for any inhaler to be efficacious: (1) the inhaler should cover the mouth and nose; and (2) it must be continuously used for as many hours as possible. The anatomical structure of the lungs lends itself peculiarly to antiseptic treatment. For some years I have been using among my patients an oro-nasal inhaler containing a mixture of formalin, chloroform, and rectified spirit, with a few drops of oil of pine or eucalyptus. The advantage of this method is that the patient can use it walking out of doors or reading, writing, or otherwise employed indoors. The success, as Dr. Ash pointed out, depends upon its continuous use, at least from four to six hours a day. Another good method mentioned by Dr. Ash is that of impregnating a chamber with volatile antiseptic substances. I use the patient's room as an inhalation chamber in preference to a special inhalation room, and have devised a vapouriser in which one or two formalin tablets with a little menthol are volatilised, the room being made more or less air-tight by shutting the doors and windows. The advantage of this method is that for hours the room is charged with formalin vapour, enabling the patient to inhale the impregnated air and rendering his clothes and his belongings in the room aseptic. The patient can use both these methods in a sanatorium or in his own house. My experience is that perseverance often results in success. But the trouble is that patients will not persevere long enough. I am, Sir, yours faithfully,

Mendip Hills Sanatorium, Wilts. C. MUTHU.

THE ROYAL DENTAL HOSPITAL: A SPECIAL APPEAL.

To the Editor of THE LANCET.

SIR,—The Royal Dental Hospital has now been established 50 years during which time an incalculable amount of suffering has been relieved and many serious illnesses averted by timely attention to the teeth of the poorer classes.

The committee of management wishes to celebrate the jubilee by making a special appeal to extinguish the debt on the building which so seriously cripples the funds of the charity. This debt was sanctioned by the Charity Commissioners and entailed a yearly payment to the mortgagees of £2,975 17*s.* 4*d.* for 30 years from 1902, of which 24 years are yet unexpired. There now remains £47,404 1*s.* 7*d.* to be paid to wipe off the debt altogether, and it is for contributions, however small, towards this sum for which the committee now appeals. This would mean a saving in the 24 years of about £33,000 in interest alone, and the money thus set free would be devoted to maintaining the hospital in a much greater state of efficiency than it is at present. It is within the knowledge of everyone that the teeth of the majority of the poorer classes are in a deplorable condition, and that a great number of the children require long and expensive treatment to save them from life-long disfigurement and inconvenience. This they can only obtain at a dental hospital. Over 100,000 operations were performed here last year, half of which were under anæsthetics.

The Royal Dental Hospital should command universal sympathy and support, not only for the benefits it has conferred on its own patients but also because it was the first dental hospital established in England, and from it all skilled dentistry in this country has developed, thus adding to the health, comfort, convenience, and happiness of all classes of the community. About 1200 students have been educated in the hospital and school. After 50 years of hard work it is earnestly hoped that this truly national institution may be freed in this, its jubilee year, from the burden of debt under which it is still struggling.

Sir Frederick Treves, Bart., G.C.V.O., C.B., LL.D., consulting surgeon to the hospital, has kindly consented to preside at a festival dinner to be held at the Hotel Cecil on June 25th in aid of the "Special Appeal Fund." Contributions may be sent to the secretary of the hospital.

We have the honour to remain,
Your obedient servants,
ROTHSCHILD, President.

CORONERS' INQUESTS UPON DEATHS DURING SURGICAL ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—In THE LANCET of April 25th, p. 1234, Dr. David Walsh has replied to my criticism of Dr. F. J. Waldo's article upon this subject which was published in THE LANCET of April 11th, p. 1106, and to his remarks I desire to offer the following observations and suggestions. In my letter I gave the exact statistics of the death-rate which the medical profession has found to be incurred by the administration of chloroform, ether, and mixtures of these two anæsthetics. These have been obtained from the records of over 1,000,000 administrations tabulated by Dr. F. W. Hewitt in his classical work on "Anæsthetics and their Administration" (third edition, 1907, p. 148). The medical profession has never expected to obtain any such information as this from the Registrar-General's reports, not only because they are imperfect from many causes, but for the reason that a figure giving only a certain number of *fatalities each year without the number of administrations* undertaken yields no material for calculating a death-rate from anæsthetics. The number of deaths under anæsthetics which occur in private practice yearly, even if published with the total number of administrations, would, according to Dr. Waldo's own showing, probably largely reduce the calculated death-rate given in my letter, and the reason for this would be that the vast majority of cases of advanced disease and severe injuries are treated by operation in the hospitals and not in private practice.

In the year 1896 the number of operations performed under anæsthetics in the operating theatre at one of the large general hospitals in London was 353; the number in 1905 was 1055. This is a very fair criterion of the enormous increase which has taken place in the number of hospital operations during the last ten years, and if the actual number of fatalities recorded by the Registrar-General for the ten years 1886–1895 was 533 and for the ten years 1895–1905 was 1269 (as given by Dr. A. D. Waller in "Science Progress," No. 8, April, 1908) the death-rate in anæsthesia has decreased in the ten years most markedly, for the proportionate increase in operations under anæsthetics is represented by the figure 3 and of deaths by only 2·38. In view of these facts there is no evidence that an increased *number* of fatalities is any measure of the risks of anæsthesia.

Dr. Waldo states that "the medical man is not compelled by any statutory obligation to report cases of death under anæsthesia to the coroner," and "in a proportion of cases which it is impossible to estimate inquests are not held by coroners upon deaths reported to them as having occurred under anæsthesia." I venture to hold the view that their discretion in this matter shows an excellent fitness for their office because (1) the reports of such inquests furnished to the Registrar-General are useless either for statistical purposes or the advance of scientific knowledge; (2) press reports of such inquests tend to increase the mortality in anæsthesia by causing unjustifiable alarm at the risk of anæsthesia in the minds of patients who are obliged to undergo operation; and (3) the public pillory of a registered medical man involved in giving evidence at such inquests who in administering an anæsthetic to the best of his ability takes every human measure to steer his patient safely through the operation causes an unfair damage to his reputation and practice which ultimately tends to make him *refuse* to administer an anæsthetic at all in desperate cases requiring operation, where his skilled help is most needed.

Let us see what the law with regard to death certification requires to protect the public from violent or unnatural deaths which would be otherwise undetected. It invokes a declaration on the part of a member of the medical profession as to the cause of death, but he is not necessarily bound to have witnessed the death. In the case of death occurring during surgical anæsthesia not only one but in almost every case two registered medical men actually present at the death can state the proper cause of death and put it upon record. The plain fact is that there can be no more need for the judgment of a coroner and jury of laymen in cases of death during anæsthesia than in those of death following after a surgical operation; both may occur under medical care and skilled attendance and can be definitely certified as to cause by two or more medical witnesses. I venture to suggest that the Coroners' Society should reconsider the question on the basis of this proposal—namely, that a death during surgical anæsthesia be considered amply accounted for by a certificate signed by two legally qualified medical practitioners, without the holding of a public inquest unless the patient's relations or those intimately concerned in the operation express some reasonable ground for dissatisfaction.

With regard to the inclination shown to desire hospital authorities to employ specialists to give the anæsthetics, there is no large London hospital without a number of skilled administrators of anæsthetics upon its staff, but it would be as reasonable to expect that a real expert can be found available to administer every anæsthetic at these institutions both by day and night as it would be to demand that the Government should only employ Royal Academicians to paint the park railings. For instance, if it were to be held that the hospital house surgeons and house physicians, who are in every case without exception fully qualified practitioners and usually are also fresh from skilled instruction in anæsthetics, were not competent persons to administer anæsthetics in the hospitals, what heaven-sent inspiration can make them more so on the day after they leave these posts and administer chloroform to their first patient in private practice? The argument could not be sustained that a registered medical man is not legally qualified to administer an anæsthetic, and any attempt to go behind his qualification in individual instances and inquire into the duration of his experience in public cannot be for the public good nor increase the safety of the public when entrusted to his care.

If some coroners, whose office unfortunately tends to make them reflect only upon the fatalities and not upon the millions of successful anæsthetic administrations, have begun to think that the teaching and opportunities for supervised practice in anæsthetic administration at the hospitals by the medical student *before* he goes up for his qualifying examinations are not as extensive as they might be, I would suggest that through the Coroners' Society they might lend most valuable assistance in supporting the memorial forthwith to be presented to the General Medical Council by the Medico-Legal Society asking for a definite enforced training in anæsthetics to be included in the student's curriculum for all medical qualifying examinations in the United Kingdom which will, if adopted, have the effect of raising the standard of skill in anæsthetic administration to be possessed by the rank and file of the medical profession.

I am, Sir, yours faithfully,
H. BELLAMY GARDNER, M.R.C.S. Eng., L.R.C.P. Lond.,
Late Anæsthetist and Instructor in Anæsthetics at Charing Cross Hospital, &c.
Harley-street, W., April 27th, 1908.

To the Editor of THE LANCET.

SIR,—I have read Dr. J. F. W. Silk's letter in your issue of April 4th and most thoroughly agree with the opinions he expresses. I wish to call special attention to statement No. 2, "In the majority of cases referred to by the coroners the primary cause of death was the nature of the accident or disease from which the patient was suffering and very remotely the anæsthetic." I think the result of my 33 years' experience in the eye department at Guy's Hospital goes far to show the correctness of this statement. With the exception of two cases of ligature of the common carotid, three or four of removal of the superior maxilla, two of trephining, eight of opening of the frontal sinuses, several for removal of orbital tumours, and a number of plastic operations on the eyelids and face taking half an hour or more for their performance, there were none in which the nature of the operation could by any chance have led to a fatal termination.

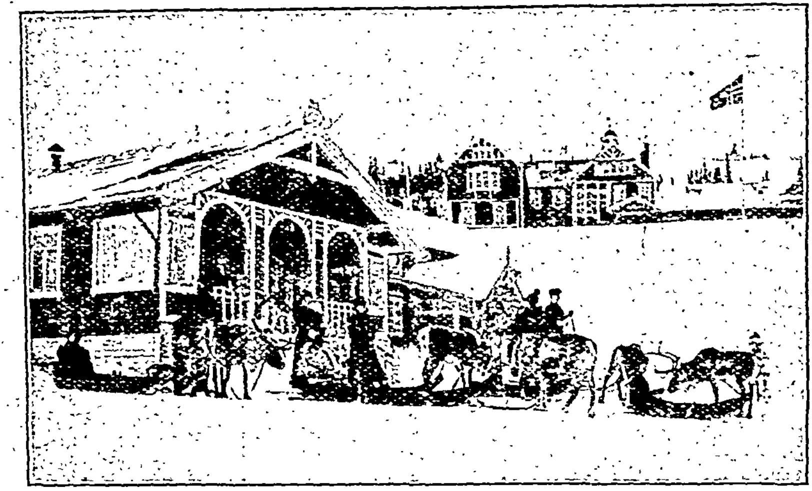
For nearly 12 years (1873 to 1885) my operations, with a very few exceptions, were performed under general anæsthesia. At the beginning of 1885 I began to use cocaine but not universally, for at first I did not believe in it and proceeded with caution; it seemed almost too good to be true. Later it to a great extent displaced general anæsthesia but by no means entirely so. I think, speaking off the book, that a very fair average of anæsthetic administrations for the 33 years would be not less than 300 a year, giving a total of nearly 10,000, a large majority of which took place during the first 12 years, during ten of which I was associated with the late Mr. Bader, and we used between us to do close on a thousand operations in the year (in one year I remember it was considerably over that number).

February of this year your Commissioner has been very much impressed with the natural advantages which Norway offers for the establishment of winter health resorts.

THE BENEFITS OF WINTER SPORT.

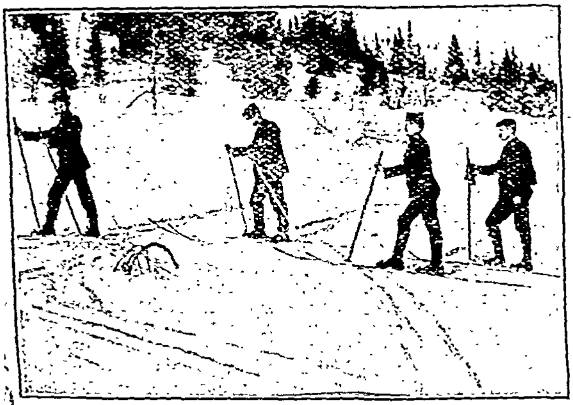
It is only of recent years that Englishmen have begun to realise the benefits of wisely directed winter sports, not only as a means for refreshing the mind but renewing the body. During recent years large numbers of town dwellers and brain-workers have snatched a few weeks for a midwinter holiday amidst the snow and ice of Switzerland. The prophylactic virtues of a winter's holiday can now be attested by many. For those desirous of breaking new ground or of enjoying opportunities for winter sports, such as reindeer sleighing (Fig. 2), Norway may be recommended as affording endless opportunities for exploration. Within the limitation of a short article it is impossible to describe adequately the fascination and charm exercised by the outdoor life and active pursuits as practised by the Norwegians. All, from the King and Queen and little Prince Olaf to the tiniest country beggar, seems to be most at home when tobogganing or ski-ing. Girls and women are keen enthusiasts for winter sports and certainly these rational forms of exercise are doing much for the development of the youth of the nation. The co-education of the sexes is thereby encouraged under the healthiest and happiest conditions. For many pampered, self-centred, delicate English children I can imagine nothing more beneficial than a winter in Norway.

FIG. 2.



Reindeer driving at mountain hotel, Trondhjem.

FIG. 3.

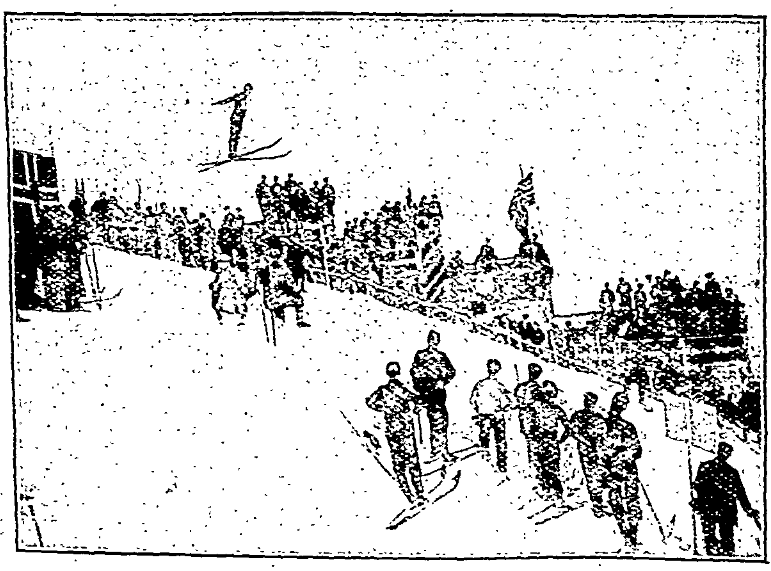


Ski-touring.

If a personal reference may be permitted as evidence of the prophylactic powers of Norwegian residence, your Commissioner may note that this is the first season for many years that he has succeeded in resisting invasion by influenza. Perhaps some annual victims of *la grippe* might consider a voyage across the North Sea, however rough, a welcome means whereby to escape an inveterate enemy.

Almost all forms of winter sports may generally be enjoyed in and about Christiania, although in up-country resorts ski-ing and some other forms may usually be had in greater fulness and extent. Ski-ing on the high mountains is a form of mental and physical enjoyment known only to Scandinavians. Winter touring on skis exercises a fascination for the young and vigorous and is an admirable means for developing nerve and muscle and character.[6] (Figs. 3 and 4.)

FIG. 4.



Ski-jumping.

---

[6] Captain Carl Roll has written an attractive, informing, and well illustrated booklet in English on "Winter Sport," which may be obtained from the Norwegian Tourist Traffic Association, 2, Storthingsgaden, Christiania. "The Winter Sports Annual, 1907-8," edited by E. Wroughton (London: Simpkin, Marshall, and Co. 1907. Price 2s.), contains much useful information respecting routes and fares to Norway and its chief sporting centres.

NOTES UPON HEALTH RESORTS.

SCANDINAVIAN WINTER HEALTH STATIONS.

(BY A SPECIAL COMMISSIONER.)

II.[1]

NORWAY'S WINTER HEALTH RESORTS.

NORWAY is well known to many as a land particularly rich in opportunities for the holiday maker and offering varied facilities for the sportsman. But its claims to be counted among the chief of European countries on account of its health resorts have not been duly recognised either in this or other lands. The fact is Norwegians themselves have only within recent years realised the possibilities of their homeland for the establishment of all-the-year-round health stations. The natural characteristics are eminently suitable but hitherto enterprise has been lacking in the opening up of the country and the provision of suitable residential establishments for visitors. The smallness of the native population and the somewhat isolated position of Norway have no doubt been in great measure responsible for the delay in the development of health centres. Now that Switzerland is being overrun with trippers of all nations it is but rational and reasonable that many should be desirous of seeking places where all the health advantages of "the playground of Europe" may be obtained without the increasing discomforts of overcrowded hotels and the disadvantage of fashionable and sports-loving manners of life. To all lovers of the simple hygienic life and to those requiring excellent climatic conditions for the winning back of health and the recuperation of strength Norway is likely to appeal more and more as its benefits become better known.[2]

A movement is now taking place in Norway which promises to make the country better known to Norwegians themselves and its many advantages realised by other countries.[3] Hitherto physicians have been slow to realise the nature of the climatic conditions prevailing in this land and the many advantages which they offer for the health seeker.

While the fjords of the west coast are best known to the ordinary tourist they by no means offer the finest climate for the health seeker. This, generally speaking, is to be obtained on the highlands and in the wide and open valleys in the inland districts, such as Valdres, Gausdal, and Gudbrandsdal. The new line between Bergen and Christiania opens up a country which should in the near future become extensively developed as centres for excellent health stations. The suggested extension of the railway from Otta to Trondhjem over the Dovrefjeld should also lead to the establishment of many desirable new health resorts.

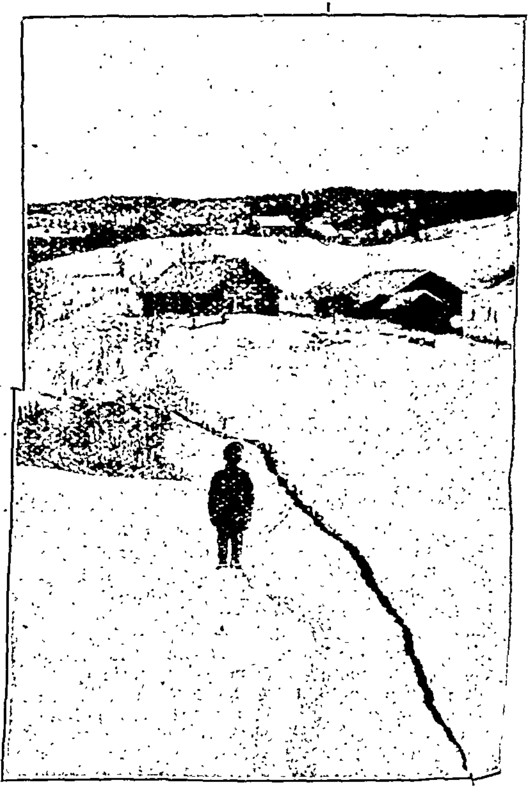
From a health standpoint the mountain climates of Norway are of particular benefit. They can be conveniently divided into (1) the high altitude or alpine climate, or as it has been well termed locally the "Hoifjeld" region, commencing at between 2500 and 3000 feet above sea level; and (2) the medium altitude, or subalpine climate, or "Hoilids" region, 1500 to 2500 feet above sea level.[4]

For some cases the valley and lowland districts offer special advantages and in summer the coast climate, in the south especially, is excellent.[5]

WINTER CLIMATIC CONDITIONS.

As it is proposed to restrict consideration to what are essentially the winter health resorts of Norway, a few words on the climatic conditions prevailing during the winter season will not be out of place. Most erroneous impressions exist in many quarters as to the nature of the weather and the manner of life existing in Norway during this time of the year, when it can offer but little evidence for its claim to be called the "Land of the Midnight Sun." Over a great part of the country snow lies from November or at all events from well before Christmas to March or on the uplands till as late as Easter. (Fig. 1.) Thus for some four or more months winter sports may be enjoyed in all their fulness and variety. Although the early mornings are dark and the nights long, the difference from England is not conspicuous except in the very northerly parts. In most of what may be called the health resort districts the winter characteristics are excellent. These are particularly noticeable in the Norwegian Highlands. Here the air is dry, clear, rarefied, and the barometric pressure low. Although keen frost may prevail the cold is but little felt and when one is wrapped up in furs causes no discomfort. In sheltered snow-covered districts but little wind is experienced. tensive forests often afford admirable protection. M more sunlight prevails than we are accustomed to in clo covered England and its luminous and actinic effects seem exercise considerable beneficial influence on many patien But little rain falls except in the west and sea-coa districts.

FIG. 1.



Winter in Norway: a ski track.

The snow descends usually in special "falls" and the lar being thus protected all dust is avoided and by reflectic the effects of the sun-light are increased and intensifie Fogs in the highland districts are rare and never produc those depressing and irritating effects which we know so we home. The air is also said to be rich in ozone an qualities. In the greater part of the country th dry and hygienically favourable.

…ed greater part of th of January anc

[1] No. I. was published in THE LANCET of April 25th, p. 1238.

[2] Dr. P. A. M. Mellbye of Christiania, with whom I discussed the question of Norwegian health stations, has published a useful reference work on the subject, "Norges Kursteder og deres Kurmidler" (Alb. Cammermeyers Forlag, Kristiania), with helpful map marking the chief "kursteder." It is to be hoped that an English edition of this informing manual may soon be available.

[3] The Norwegian Tourist Traffic Association (Forening for Reiselivet i Norge), 2, Storthingsgaden, Christiania, under the able and enterprising direction of Mr. H. Malling, to whom your Commissioner is indebted for much kindness and information, is doing much for the opening up of Norway. The association publishes a useful "List of Hotels, Sanatoria, and Skyds Stations" and all visitors to Norway would do well to avail themselves of the publications and assistance of this valuable organisation.

[4] *For much valuable* information regarding climatic meteorological data see "Norway as a Winter and Resort," by Dr. A. Magelssen. *English edition,* John Sörensen of Tofte Sanatorium.

[5] Prospective visitors to Norwa interesting and informing Year Strand, W.C.

who had had the rare good fortune to be assistants to Professor Cleland. They made the presentation as a token of their gratitude and admiration for Professor Cleland. He had been to them their great master. He had in a profound manner influenced the lives for good of all who had come into association with him and he had ever held up before them an ideal of science viewed from the purest and loftiest aspect, and he had also taught them to seek for truth and beauty at one and the same source. The museum had been entirely the work of Professor Cleland and it was fitting that within the building there should be a memorial of him who created it.

Hospital for Skin Diseases, Glasgow.

At the annual meeting of subscribers to this hospital regret was expressed at the loss sustained by the hospital in the death of Sir Thomas McCall Anderson, to whose distinguished services since its foundation the hospital owed its success and fame. During the past year 1915 new cases were admitted and 83 cases were treated in the wards of the Western Infirmary connected with the hospital. Since the foundation of the hospital in 1861 63,411 patients have received outdoor treatment, and since the opening of the Western Infirmary 33 years ago 3208 patients have benefited by indoor treatment. 89 students attended the clinique during the summer session.

Braemar Parish Council: Medical Officership.

The Crathie and Braemar parish council met on April 21st when the question of the medical officership was again under discussion. It is understood that several applications for the vacant post were received. After discussion it was agreed that no appointment should be made meantime but that a subcommittee of three members should be appointed to endeavour to get a suitable man to apply. The present medical officer's appointment expires on April 30th, so that in all probability the parish will be without a fund medical officer and consequently will lose the medical relief grant.

Death of Miss Rachel Lumsden, Aberdeen.

The death occurred at Aberdeen on April 22nd of Miss Rachel Frances Lumsden, formerly superintendent of the Royal Infirmary of Aberdeen. Miss Lumsden, who belonged to a well-known Aberdeenshire family, received her training in London. In 1877 she was appointed honorary superintendent of the newly established Hospital for Sick Children in Aberdeen and with such conspicuous success did she carry out the duties of this post that when in 1885 she offered to undertake the office of superintendent of the Royal Infirmary at a critical period in its history great satisfaction was everywhere expressed. Her services at both these institutions were rendered without fee or reward of any kind. Under her management the nursing became entirely reorganised. In 1897 when she retired after 12 years' service she was the recipient of an address engrossed in a beautiful album and signed by all the gentlemen in the medical profession in Aberdeen connected with the University, the infirmary, Sick Children's Hospital, and other public charities. Miss Lumsden was appointed by the late Queen Victoria a member of the council of the Scottish Board of the Queen Victoria Jubilee Institute of Nurses. She was also one of the leading members of the Royal British Nurses' Association, and the first lady to organise a Scottish hospital on the English system of admitting probationers for a three years' training under the direction of sisters.

April 28th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish University Bill.

Mr. Birrell's University proposals have excited very considerable interest in Cork and the South of Ireland generally. When the text of the Bill was published several letters appeared in the local press criticising the provisions of the measure as they affect the Cork Queen's College. It was pointed out that from Mr. Birrell's explanatory statement it appeared that a special grant of £10,000 would be given to the Cork College but that in reality such was not the case as professors' pensions and the cost of maintaining the buildings, &c., which are now defrayed out of Parliamentary grants, would in future be provided for out of College funds, that in fact the Treasury proposed giving with one hand and taking away with the other. Stress was also laid on the evils of a federal university, a system which has been tried and found wanting in England. Attention, too, was specially directed to the advantages which Dublin students have at the Royal University over all others owing to their being in touch with the examiners, and it was urged that the establishment of a university for Munster would be the only means of getting rid of that difficulty. Accordingly several public bodies pronounced in favour of a separate university for the South of Ireland. The Cork town council and the Cork board of guardians passed unanimously propositions urging the Government to convert the Cork Queen's College into a university. The Lord Mayor of Cork and the chairman of the Cork county council summoned a meeting of the people of Munster to discuss the provisions of the Bill and on Saturday last a very large and particularly representative meeting was held in the City Hall, presided over by the Earl of Bandon, His Majesty's Lieutenant of the county of Cork. The first speaker was Mr. William O'Brien, M.P., who recently offered £50,000 towards the establishment of a university in Cork. In the course of an eloquent address he expressed the conviction that a university in Cork would alone meet the educational requirements of the people of the South of Ireland, but he felt convinced that there is no chance of engrafting such a proposal in the present Bill though later a university was sure to come. Accordingly, he recommended that the Bill should not be wrecked but that an endeavour should be made in Committee to improve it as far as the Cork Queen's College is concerned. He then proposed a motion that no settlement of the university question could be regarded as final which did not provide for the establishment of a university for Munster. The motion was seconded and carried with acclamation.—The Committee on Public Questions, Rights, and Privileges, composed of ministers and laymen representing the Methodist Church in Ireland, has published a series of resolutions protesting against Mr. Birrell's University Bill on the grounds of its endowing denominational universities, because of its curtailment of the privileges enjoyed by Methodists in the Royal University in depriving them of adequate representation on the Senate, and because of its doing away with extern students. The committee has asked the Chief Secretary to receive a deputation to hear from it more fully the views of the Methodist Church in Ireland on the university question.

The Re-foresting of Ireland.

It is a remarkable fact that Ireland, which was in olden time known as "the Isle of the Woods," is now the least wooded of all north-western countries, with the single exception of Iceland. The report of the forestry committee appointed by the Department of Agriculture has just been published and shows that while Austria leads off with a 32 per cent. surface of forest cover, and Denmark—a purely agricultural country—presents 7 per cent., England has 5·3 and Scotland no less than 4·6; while the ragged remnant of its forest foliage covers but 1·5 per cent. of the surface of Ireland. The question of re-foresting has now been vigorously opened. It has received the favourable attention of their Excellencies the Earl and Countess of Aberdeen and Mr. Charles Dawson, a former Lord Mayor of Dublin, is an enthusiast in the movement. It is claimed that the presence of forests has a beneficial effect on climate and, further, that on the elevated portions of the country's surface the very existence of the soil depends on their presence, without which the process of weathering never fails to lay bare in time the skeleton rock. The advocates of the movement further hope that it may lead to the establishment of a substantial timber industry and promote in other ways the health and wealth of the country.

School Attendance in Dublin.

There has been a marked irregularity in school attendance by the Dublin children recently. The unusually cold weather had undoubtedly something to answer for; so had the recent return of the "spotted fever" scare. It has also been urged that the school rolls do not adequately represent the school-going age of the section of the population in question. The fact has, however, come to the surface that there is an approximate average absence from school every day of one in four of the children enrolled. This represents a daily item of 11,000 non-attendances. The report of the school attendance committees for 1907 states that the inspectors might accomplish their mission if the occupiers of the

WALES AND WESTERN COUNTIES NOTES.

(From our own Correspondents.)

Diphtheria in Holywell.

At the last meeting of the Holywell (Flintshire) rural district council Mr. James Williams, one of the medical officers of health, called attention to the large amount of sickness among school children and said that a great deal of it was due to imperfect scavenging and to the large accumulations of filth at many of the houses. The conditions which he had found were a disgrace to the owners, to the occupiers, and to the sanitary authority. At a previous meeting, when eight cases of diphtheria were reported upon as having been notified during the month of March, the district council sought to minimise the seriousness of the outbreak by reflecting upon the *bona fides* of the medical practitioners who certified the cases, one member of the council remarking that "if a person had a sore-throat it was diphtheria right away; the mistake was the half-crown notification fee." It is a pity that the difficulties which sanitary officials have to contend with when endeavouring to check an outbreak of infectious disease should be increased by the passive opposition of the very persons who ought to render assistance. It is indifference of such bodies as the Holywell rural district council which made it possible for Sir John Dickson Poynder's Committee to recommend the transference of certain administrative powers to the county councils.

Infantile Mortality in Newport.

As the result of a conference recently held at the Newport (Mon.) town hall it has been decided to form a ladies' public health society upon the lines of the organisation which has for many years done such good work in Manchester. The primary object of the newly formed society is to coöperate with the sanitary committee of the corporation in its attempt to lessen the amount of infantile mortality in the borough. A female health visitor has been employed by the committee for more than five years and in his last annual report the medical officer of health (Dr. J. Howard-Jones) pointed out that the substantial reduction in the infantile mortality rate during the previous five years ought to encourage the corporation to take still further action in instituting preventive measures. At the conference referred to it was decided to establish a fund for the purpose of providing proper nourishment for expectant mothers who were not qualified to receive Poor-law relief.

Medical Inspection of School Children.

The Gloucestershire county council has appointed Dr. J. Middleton Martin as a whole-time medical officer of health and to undertake, with assistance, the medical inspection of the school children in the county. The Carmarthen town council has appointed Mr. L. M. Bowen-Jones, the medical officer of health of the borough, as medical inspector of school children. There will be about 600 children to be inspected each year and the payment proposed to be made is at the rate of 1*s*. for each child. A suggestion was unsuccessfully made that the payment should be 2*s*. per head, while a proposal that it should be 6*d*. met with but scant support.

The Notification of Whooping-cough.

There are so few districts in which whooping-cough has been continuously notifiable that the results obtained are always of interest. The disease has been included in the list of diseases notified in the rural district of Llandaff and Dinas Powis since the adoption of the Infectious Disease (Notification) Act in 1890. There were notified last year 186 cases, and six children, all under eight months old, died. Dr. Richard Prichard, the medical officer of health, in his annual report suggests that the council should consider the desirability of utilising some part of the newly erected isolation hospital for the purpose of isolating patients suffering from whooping-cough. Unless some such course as this is taken he considers that he would not be justified in recommending the continuance of the disease among those compulsorily to be notified. It would be a pity if any precipitate action were taken in this direction, for even without the means of isolating patients much good can be done by the timely visits of an inspector and especially if the inspector is a woman. The case mortality from whooping-cough in the rural district in 1907 was 3·2 per cent. and in the preceding ten years it was 5 per cent.

The McAlpin Nursing Home, Glasgow.

The new buildings in connexion with the McAlpin Nursing Home were formally opened last week by Lord Inverclyde. This marks a new epoch in the history of nursing homes in Glasgow. The home was first started in 1874 in a humble way. It was the pioneer nursing home in Glasgow and led the way to an immense improvement in the housing and treatment of private patients, especially those who had to come from the country to undergo an operation. From its inception this institution has done a great deal of charitable work, over one-third of the patients, it is stated, being treated at considerably less than cost. Although the home has recently been incorporated no part of the income can be paid away in dividends. Any surplus accruing is to be expended on reducing the fees to those charged less than the cost of their board and nursing and in extending the institution. The new building has been specially designed and constructed for the purpose of a nursing home and contains accommodation for 24 patients in single and private rooms, six in double rooms, and two wards of six beds each. All the principal private rooms have a southern exposure and each one is provided with a separate outside balcony. The operating theatre is fitted up on the most modern lines and the building is fire-proof throughout.

The University of Glasgow "Commemoration Day."

A most interesting and attractive gathering took place at Gilmorehill on April 24th, when the University celebrated its Commemoration Day. Not only did graduates from all parts of the country return to pay homage to their *alma mater* but representatives from sister universities and from the town council were also present and helped to make the assembly a representative one. After Principal MacAlister had read the commemorative preface an oration was delivered by Professor Gray on Lord Kelvin, the late Chancellor of the University. Thereafter honorary degrees were conferred by the Vice-Chancellor. Colonel David Bruce *in absentiâ* received the degree of LL.D. for his researches in connexion with Malta fever, tsetse fly disease, and sleeping sickness. The same degree was conferred upon Dr. J. C. McVail, who for the past 18 years has been medical officer of health of the counties of Stirling and Dumbarton. In the evening the commemorative dinner was held in the Bute Hall. It was attended by over 200 ladies and gentlemen. The principal guests of the evening were the honorary graduates of the day.

Honour to Glasgow Professors.

Last week an interesting presentation took place to Dr. J. G. McKendrick, late Professor of Physiology at the University of Glasgow. It consisted of a portrait for the University by Mr. J. H. Lorimer, R S.A., a sum of £450 for the equipment of the Laboratory of Experimental Psychology in the new physiological buildings, and a silver tray as a personal souvenir. The portrait and the tray had suitable inscriptions. The movement originated a year ago in the business committee of the general council, which thought that a mark of respect should be paid to the Professor of Physiology on the occasion of his retirement. In his reply Dr. McKendrick referred to the 30 years of his professorship in Glasgow, during which time more than 4000 students had passed through his hands. Since 1876, when he became professor, something like £17,000, in addition to the sum expended on new laboratories, probably amounting to £20,000 more, had been contributed for the physiology department. The result of this was that the dream of his life had been fulfilled. Referring to the recently established lectureship of Experimental Psychology Dr. McKendrick said that was a subject in which he had always been interested. This lectureship was intended to deal with the investigation by physical methods, so far as it was possible to apply them, of the action of the organs of sense, the nervous processes in general, and of the nervous processes in connexion with sensation, perception, emotion, choice, and even certain mental acts. As a subject experimental physiology and psychology lay between physiology and psychology connecting one with the other. Another interesting presentation was made to the University by Principal J. Yule Mackay. This consisted of a bronze medallion of the head of Professor Cleland, to be preserved permanently in the anatomical museum of the University. He made the gift, he said, on behalf of 17 men elaboration of the blood, the normal development of the bones, the normal nutrition of the hair, of the skin, of the subcutaneous adipose tissue; nay, certain traits of character, shown in tendencies intellectual or moral, are in close dependence on its function. Accordingly, in cretinism we find the thyroid to have undergone alterations which, from degenerative forms more or less complex represented by goitre (cases of 'goitrous cretinism') go on to the arrest of the development of the gland itself (cases of 'non-goitrous cretinism')—all the cases in question being coincident with perversion or suspension *of function in the thyroid*." Italy, according to recent statistics, numbers 15,000 cretins, but that total is far below the truth. Besides the registered cases there exist many others in which the *ensemble* of symptoms being "incomplete" escapes the diagnosis of the layman, only the intellectual manifestation of the disease being apparent, but which all the same are cases of "cretinism" pure and simple. Such a malady, overt or masked, Italy must spare no effort to combat. What are the weapons available? There are two, differing in kind. The first takes cognisance of the conditions under which the malady develops. This development (*sviluppo*) is intimately connected with the quality of the drinking water, which contains principles acting directly in the adult, indirectly in the infant (through the nurse's milk), on the thyroid gland, the structure of which they alter and *the normal evolution* of which they inhibit. These principles have yet to be discovered, and until this is done the *remedy is obviously to provide the infected locality* with water possessing a good record as supplied to non-cretinous communities. The *second weapon in combating the disease* is the administration to the sufferers of the well-known preparation from the thyroid of the *lower animals—the* preparation elaborated by Ganghofer and Wagner, whose experiments, checked and confirmed *by Professor Tedeschi* himself, have put it beyond doubt "that in this weapon we possess a means of cure as effective in cretinism as quinine is in malaria." Hundreds of children, continued the lecturer, in Italian as in Swiss practice, have been *cured* by this means in a few weeks—changes physiological and psychological having thus been wrought in cases which seemed doomed for life "to obfuscation of the mind and to decrepitude of the body." Professor Tedeschi concluded his loudly applauded lecture by an appeal to his compatriots, professional and lay, to give the Government no rest until the two weapons above mentioned have been vigilantly and vigorously put in operation in the cretinous districts. A committee *ad hoc* has indeed been formed, its president being Professor Mangiagalli, with Professor Belfanti, Professor Devoto, Professor Foa, and Professor Tedeschi himself as assessors. *Quod felix faustumque sit!*

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

A Successful Case of Talma's Operation.

Dr. Albrecht showed at a recent meeting of the Medical Society a man who had been suffering *from* alcoholic cirrhosis of the liver and on whom Talma's *operation* was performed in January, 1906. The previous history was to the effect that eight months before the operation icterus and *ascites* had been noticed and œdema of the legs soon incapacitated him. At the operation an incision about six inches long was made across the abdominal wall parallel with the left costal arch and the omentum and the lower extremity *of the* enlarged spleen were sutured to the abdominal wall. There was troublesome hæmorrhage on account of the friability of the spleen, but this was stopped by packing and the wound in the skin was partially *closed*. *In the first few* weeks after the operation the ascites reappeared, but two months later the patient himself noticed *that the* circumference of his abdomen had diminished. He could now resume work and became an omnibus conductor, in which occupation he jumped on and off the vehicle many times a day without experiencing any ill-effect. Two years after this operation the *patient* presented himself to have an operation performed for hernia. He said that there had been no return of the œdema in his legs and *there* was at that time *only* a *little* ascites still present. The collateral circulation was established and the caput Medusæ *formed by* the anastomosis and *enlargement* of the inferior epigastric, the mammary, the intercostal, and the thoraco-epigastric veins was clearly demonstrable. The case was interesting because some authorities believed icterus to be a contra-indication for Talma's operation. The technical aspect of the operation also deserved notice because the spleen was resorted to for the purpose of establishing collateral circulation. Ito and Omi have shown that the omentum alone was not sufficient in all cases. The results of Talma's operation were very favourable. At present most surgeons found that about 33 per cent. of the cases recovered, 33 per cent. were improved, and the remainder were not benefited. Dr. Albrecht believed that if the operation were performed more frequently the larger experience thus gained would make the indications for it clearer and would lead to still better results.

A Proposed Central Board of Public Health.

In the last session of the Austrian House of Lords Privy Councillor Professor Ludwig (professor of medical chemistry in the University of Vienna) moved a proposition asking the Government to bring in a Bill which would *extend the existing* statutes on the subject of public health and also to order the formation of a Central Board of Health. *The proposed* Bill would provide that all the scientific institutes necessary for carrying on the work of the medical *officers of* health should be adequately endowed, that these officers should have facilities for keeping in touch with the latest discoveries of science and for attending post-graduate courses of instruction, and that their official position should be improved so as to induce the best men to seek these appointments. In supporting the proposal he pointed out that Austrian sanitary institutions were at present rather behind the times, that the grants available for them had been fixed too low by the financial authorities, and that many departments of public importance dealing principally with medical questions were not controlled by medical men.

Compression of the Vena Cava Superior by an Aneurysm of the Aorta.

Dr. Weinberger recently described the case of a man who had contracted syphilis 18 years ago and who had for the last six months suffered from pain in the arms and swelling of the face and upper part of the trunk. At present he was affected with cyanosis and œdema, which reached as far as the costal arches in front and to the lumbar region behind, whilst the lower part of the body was free from œdema. The cyanosis was also well marked on the visible mucous membranes. The cutaneous veins of the upper part of the body were dilated. On both sides of the sternum there was a region which gave a dull percussion note and also pulsated a little, whilst on the x ray screen a shadow having a movement of pulsation was visible. On these grounds an aneurysm of the arch of the aorta was diagnosed. Dr. Weinberger believed that the aneurysmal enlargement was compressing the vena cava superior, but it was not impossible that a perforation of this vein by the aneurysm had already taken place, producing an arterio-venous aneurysm. He said that either condition would be accompanied by the extreme cyanosis seen in the patient, but at present there was no means of making a differential diagnosis between them even with the aid of the x rays.

(FROM OUR OWN CORRESPONDENT.)

Rights of Working Women.

THIRTEEN years ago the Supreme Court of the State of Illinois decided that a State could not, under the Federal constitution, restrict the working hours of adult women. This decision has had the effect of retarding legislation in favour of working women in this country, though two or three States have been governed by the decision of the highest court of Massachusetts which sustained the constitutionality of a law providing a ten-hour day for women. The question has finally come before the Supreme Court of the United States, which unanimously holds that the working hours of women may be restricted for the protection of health and that the welfare of the State depends upon such restriction. It maintains that the two sexes differ in structure of body, in the functions to be performed by each, in the amount of physical strength, in the capacity for long-continued labour, particularly when done standing, in the influence of vigorous health upon the future well-being of the tenement houses were permanent residents, but the greater proportion of them are a kind of floating population depending on chance for a living and being unable to pay their weekly rent are ejected and remove to some other district there to undergo a similar process of ejection in due course. This migratory style of existence is both baffling and disappointing to the best efforts of the school attendance officers and the extent to which it is indulged in can be imagined when it is stated that there are upwards of 250 ejectment cases disposed of in the police courts weekly. It illustrates one of the special evils of tenement-room residence in which no healthy human tissue-fibre—physical, moral, or intellectual—can possibly flourish.

Women's National Health Association for Ireland.

In the Women's National Health Association for Ireland the Countess of Aberdeen appears to have succeeded in an effort in which all preceding political philanthropists had failed—that of bringing together all creeds and classes with the common object of improving the physical conditions of the victims of disease and of poverty—with the ignorance contributory thereunto. Dr. Shamus O'Brien has been set free, by special arrangement, from his duties as dispensary medical officer for the purpose of giving courses of lectures in Irish to the inhabitants of Irish-speaking districts. A committee has been formed with the special object of sustaining his efforts, and the association is very appropriately represented thereon in the person of Dr. Michael F. Cox, senior physician to St. Vincent's Hospital, Dublin, who is a county Roscommon man by birth, and possesses a rare knowledge of Irish history, archæology, and folk-lore. Some of the Registrar-General's valuable diagrams have been prepared with Gaelic texts; and pathological specimens, with coloured diagrams, have been contributed by Professor E. J. McWeeney and Professor A. E. Mettam (of the Catholic University Medical School and the Royal Veterinary College respectively), who are also members of the committee of the Women's National Health Association.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Fat Treatment of Diabetes.

M. Maignan read a paper before the Biological Society on April 11th in which he submitted that the only food-stuffs completely used up by diabetic tissues are the fats, because they are the only bodies which do not form sugars in their disintegration. For the subjects of this disorder carbohydrates ought to be forbidden as far as possible, proteins reduced to the minimum—that is to say, to the lowest quantity absolutely necessary for the body's metabolism—and these food-stuffs should be replaced by the fats. M. Maignan, working with M. Arloing, has tried this treatment upon diabetic patients and obtained results similar to those which they had observed in dogs—namely, the disappearance of the sugar, the diminution of the urea and acetone excretion and of the quantity of the urine, the restoration of the patient's vigour, and the immediate arrest of the bodily wasting in severe cases.

The Clinical Employment of Ethyl Chloride as a General Anæsthetic.

The most frequent cause of death during general anæsthesia is syncope, either of toxic or of nervous origin, according to a paper read by M. Camus at the same meeting. He accordingly urged that chloride of ethyl should be employed with slow and progressive dosage. He uses for this purpose a specially constructed mask and is able to induce complete anæsthesia with very small doses (as a rule of from one to three cubic centimetres) in the space of two minutes. The requisite quantities of the drug are put up in glass capsules prepared beforehand and administered first at a temperature of zero, with subsequent gradual warming. This method allows of the better control of the rate of evaporation and avoids the risks of asphyxiation or of toxic complications. The typical clinical picture of anæsthesia is produced gradually and in the same manner the state can be maintained with safety and accuracy.

The Action of Bicarbonate of Sodium on Gastric Secretion.

M. Linossier and M. Lemoine at the Academy of Medicine on April 15th recapitulated the observation which they made as far back as 1893 that bicarbonate of sodium stimulates gastric secretion in whatever doses and at whatever time it is given, but that its action varies according to the activity of the secretory process. Recent experiments confirm this statement, and they find that its effect on the stomach is in inverse ratio to the richness of the gastric juice in hydrochloric acid, being very marked in subjects with less than the normal output and scarcely appreciable in persons with marked hyperchlorhydria.

Disease in the Army.

The following figures are extracted from a recent return of the incidence of disease in the army for the period 1900 to 1905, both for the home and African troops. In the home army influenza accounts for 21 per cent. of the total sick lists; the enteric fever returns form 3·7 per cent.; measles, 18 per cent.; scarlet fever, 8 per cent.; malaria, 15·2 per cent.; dysentery, 1·66 per cent.; tuberculosis, 5·9 per cent.; broncho-pneumonia and capillary bronchitis, 3·8 per cent.; pleurisy, 7·64 per cent.; inflammatory conditions of the throat, 69 per cent.; and venereal diseases, 29·1 per cent. In Algeria the figures are different: influenza, 5·1 per cent.; enteric fever, 11·2 per cent.; measles, 12·2 per cent.; malaria, 12·8 per cent.; dysentery, 7·66 per cent.; tuberculosis, 5·9 per cent.; bronchitis, 3·6 per cent.; pleurisy, 5·9 per cent.; inflammatory conditions of the throat, 34·7 per cent.; and venereal diseases, 72·2 per cent. There is a slight diminution in the occurrence of nearly all these diseases except the last two mentioned.

April 28th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Cretinism.

IN Milan, before a post-graduate audience, reinforced by many of the lay public, Dr. Vitale Tedeschi, professor of children's diseases in the University of Padua, has just delivered a lecture "Sulla Lotta contro Cretinismo" (on the Struggle against Cretinism)—a struggle, I may add, which is only at its initial stage against a malady long endemic in Italy. Cretinism, he set out by remarking, used to be regarded as a special form of degeneration, congenital or hereditary, similar in nature to idiocy. Latter-day science, on the contrary, holds that, in the production of the cretin, degeneration and heredity are only accessories. "Cretinism," continued Professor Tedeschi, "is, *per se*, a true and specific disease." This position he proceeded to fortify by experimental data which go to prove that cretinism is not manifested before the sixth or eighth month of life, and that, moreover, the ancient opinion was well founded according to which a determining factor in the etiology of cretinism is the quality of the drinking water. This opinion has been confirmed by recent research showing the causal connexion between the cretinism of certain communities and the composition of the water which they consume—cretinism appearing for the first time in localities supplied with drinking water from a new source, identical in quality with that imbibed in the regions subject to the disease; and, on the other hand, disappearing from the latter when the water has been introduced from a fresh and traditionally sound reservoir. In further confirmation of this position, Professor Tedeschi instanced cases of *neo-nati* brought from immune districts, and belonging to families equally immune, contracting the disease when put out to nurse in an infected locality. While these are facts inductively established, chemical analysis of the incriminated water has as yet disclosed nothing to account for the disease. Cretinism, according to the findings of hydrographic research in the infected districts, is often manifested in close connexion with goitre; nay, we see in those districts a direct parallelism between the frequency and intensity of goitre and the frequency and intensity of cretinism. The element common to the two is constituted by alteration, structural and functional, in the thyroid gland. This organ was, until a few years ago, an *opprobrium physiologiæ*; now it is recognised as one of the most important organs of the human body. "It is," continues Professor Tedeschi, "the grand regulator of 'growth' in the largest sense of the word—of 'growth' in the intellectual as well as in the physical sphere. Of great organic changes it is always the concomitant, undergoing modifications in all the leading phases of organic life—phases more or less intimately, more or less nearly, connected with the reproductive functions. On its integrity depend the normal inspiring hope in the minds of his patients. His third clinic will most likely be divided amongst the other two clinics, as it was instituted only *ad personam.* His sudden death cast a gloom over the proceedings of the Congress of Rhinology and Laryngology and the business was suspended for an hour as a sign of mourning, a longer adjournment being considered inexpedient on account of the number of foreign visitors. A deputation from the congress was present at the funeral.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced:—Dr. Furquim Werneck, an eminent obstetrician and gynæcologist of Rio de Janeiro, aged 62 years. He represented Brazil in European medical congresses and took a very prominent part in the sixth Brazilian Congress of Medicine and Surgery held at S. Paulo. While a student Dr. Werneck took part in the military operations against Paraguay and later found his early military experience of considerable value during debates in the Federal Congress, of which he was a distinguished member.—Dr. Ludwig Karl Schmarda, emeritus professor of zoology in the University of Vienna, who if he had lived a little longer would have completed his ninetieth year. In early life he was professor of zoology in the University of Gratz but during the political troubles of 1848 acted as surgeon to the military hospitals. After this he was appointed to the chair of zoology in the University of Prague but after four or five years resigned the post and started on a long expedition for scientific observation, during which he visited New Zealand and many parts of South America. For some time after his return he seems to have been disapproved of by the authorities in consequence of his publishing, in collaboration with Professor Unger, a treatise on zoology which was branded as atheistical by the Ultramontane party but in 1862 the University of Vienna elected him to the chair of zoology, which post he filled until some 25 years ago, when he retired. The scientific world is indebted to Professor Schmarda for a number of manuals and monographs on zoological subjects and for a detailed account of his scientific travels in three volumes.—Dr. Franz Mracek, extraordinary professor of dermatology in the University of Vienna, at the age of 60 years. He was in early professional life assistant to Professor Sigmund and afterwards *Primararzt* at the Rudolf Hospital. His best-known works are a Manual of Skin Diseases with numerous plates and a monograph on Syphilis of the Heart.—Dr. Moriz Liebmann, *privat-docent* of midwifery and gynæcology in Budapest.—Dr. Franklin W. Hays, professor of medicine and of dermatology in the Medical College of Indiana, Indianopolis.—Dr. Erwin Herter of Berlin, author of numerous papers on Physiological Chemistry. He was for two years in charge of the chemical department of the Zoological Station at Naples. His age was 58 years.

Medical News.

University of Oxford.—The following candidates have been approved at the examinations indicated:—

Preliminary.

Animal Physiology.—G. H. Alington, Trinity.

Zoology.—H. G. Barnes, Christ Church; W. A. Barr, Exeter; J. H. Beattie, Corpus; C. M. Burrell, University; E. W. Carrington, Keble; J. C. Davies, New; C. Dean, Trinity; R. C. Fairbairn, Exeter; R. A. D. Gillis, St. John's; D. B. J. Hallett, University; R. S. A. Heathcote, New; H. S. Knowlton, Keble; G. A. Maling and E. E. Mather, Exeter; Hon. P. A. Methuen, New; J. C. Moulton, Magdalen; A. L. Pearce-Gould, Christ Church; T. L. Price, Keble; N. D. Pringley, Lincoln; M. O. Raven, Trinity; F. C. Reynolds, New; A. S. Robinson, Exeter; E. R. Speyer, New; G. B. Tarring, Merton; F. J. Tear, non-collegiate; T. O. Thompson, St. John's; B. H. Walker, Queen's; and W. W. Waller, New.

University of Cambridge.—The following have passed the examination in Sanitary Science:—

W. Anderson, A. W. G. Bagshawe (Caius), A. Beeley, J. M. Bernstein, J. Brunton, W. J. Corbett, W. F. Corfield, R. M. Courtauld (Pembroke), A. M. Jukes, S. J. Killen, H. C. T. Langdon (Caius), F. T. C. Linton, T. C. Lucas (Clare), J. F. Macdonald, A. Mathieson, Mabel L. Ramsay, C. D. Rankin, T. S. Ross, Sophie Seekings, E. P. Sewell (Pembroke), D. Stiell, T. Strain, T. W. Wade, and W. N. Walker.

The Linacre lecture will be delivered by Professor W. Osler, M.D. Oxon., F.R.S., on Wednesday, May 6th, at 5 p.m., in the new museums. The subject will be: Thomas Linacre, his life and works.

Society of Apothecaries of London.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—E. M. Adam (Sections I. and II.), Charing Cross Hospital; O. C. Andrews, Birmingham; A. J. K. Brayton (Section I.), Liverpool; J. Brierley (Section I.), St. Thomas's Hospital; A. C. J. Elwin (Section II.), and F. S. Hawks (Sections I. and II.), King's College Hospital; H. E. Middlebrooke (Section I.), London Hospital; L. G. Powell (Sections I. and II.), Royal Free Hospital; J. V. Steward (Sections I. and II.), Manchester; and N. C. Wallis (Section I.), London Hospital.

Medicine.—A. J. K. Brayton (Sections I. and II.), Liverpool; W. J. G. Gayton (Section II.), London Hospital; F. S. Hawks (Section I.), King's College Hospital; J. K. A. Helm (Sections I and II.), Guy's Hospital; J. Jones, Manchester; J. M. Murray (Section I.), Royal Free Hospital; C. S. Ormsby (Section II.), St. George's Hospital and Edinburgh; P. D. Pickles (Sections I. and II.), Leeds; S. Speelman (Sections I. and II.), Amsterdam; and H. B. Waller (Section I.) London Hospital.

Forensic Medicine.—A. J. K. Brayton, Liverpool; W. C. D'Eath, Charing Cross Hospital; J. K. A. Helm, Guy's Hospital; J. Jones, Manchester; J. M. Murray, Royal Free Hospital; C. S. Ormsby, St. George's Hospital and Edinburgh; and F. H. P. Wills, St. Mary's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—A. C. J. Elwin, J. Jones, C. S. Ormsby, P. D. Pickles, L. G. Powell, S. Speelman, and J. V. Steward.

University of Edinburgh.—The following is the official list of passes at the recent professional examinations for degrees in Medicine and Surgery:—

First Professional Examination.—Herbert F. W. Adams, G. A. Melville Anderson, Sidney H. Arthur, Madan Mohan Lal Atal, Clement C. Cafferata, Samuel B. B. Campbell (with distinction), William J. Candlish, Peter W. Carruthers, Allan L. Christie, Asher Cohen, Frank Eley Crew, James H. Cuthbert, Thomas C. Dallas, John P. Davidson, Frederick B. Dreyer, Harry Evans, Stanley Fenwick, Margaret Ferguson, John Gifford, B.A., John G. Gill, William L. Glegg, Robert A. Greenwood, John W. C. Gunn, M.A. (with distinction), Mary I. Hemingway, James A. Henderson, Herbert D. M. Imrie, William N. W. Kennedy, A. Mirza Raza Khan, Maurice B. Lawrie, Harry Lewis, George J. Linklater, Stanley J. Linzell, Joseph M'Caig, Peter M'Cowan, William Macdonald, Eric F. W. Mackenzie (with distinction), Henry M. M'Kenzie, William S. M'Laren, George G. Marshall, James Maxwell, Walter Mercer, Hugh S. Palmer, Hugh F. Penman, Francis G. Power, William A. Rankin, Archibald Romanes, M.A., William Rose, M.A., William J. Rosie, James N. M. Ross, Agnes Rothé, Mossie Rougvie, William M. W. Shepherd, Alan W. S Sichel, B.A. (with distinction), John T. Smeall, William R. Stewart, James R. K. Sutton, Meyer Teitelmann, Garth ap-Thomas, Ruby Thomson, John S. Tomb, Benjamin Weinbren, Harry Whitaker, and Arthur R. Wightman.

Second Professional Examination.—Old Regulations: Major George Bidie, I.M.S. 1892 Ordinance (three subjects): Peter Allan, Francis G. Bell, Walter Bisset, M.A., B.Sc., Uriah F. F. Brown, George R. Bruce, M.A., Gilbert Burnet, Joseph le F. C. Burrow, Walter W. Carlow, M.A., William Darlington, Wilfred J. Feltham, Annie G. Fergus, Eion L. Ferguson, John B. Ferguson, François P. Fouché, Robert W. Greatorex, Edward B. Gunson, Thomas E. Guthrie, Hugo F. G. Hall, W. R. Clayton Heslop, John Honeyford, Alfred E. Huckett, Gideon J. Joubert, Thomas D. Kennedy, David T. M. Large, John P. Litt, John M. Logie, A. Sinclair Loutit, D. Murray Lyon, Wilfrid V. Macaskie, Thomas M'Fetridge, John R. M'Gregor, William Macnaughton, Ram C. Malhotra, Sesi Marshall, Daniel B. Maunsell, William A. Miller, B. Branford Morgan, Oliver A. J. N. Muriset, Harry G. G. Nelson, Pieter J. Olivier, Dora E. Paterson, Peder N. Pedersen, Stanley Pinion, Stephen H. Paga, William D. Reid, Christopher Rogers, William A. Shafto (with distinction), Fraser M. Sinclair, John Stevenson, Claude B. Tudehope, Stephen H. Wilkinson, and Guy A. Wyon, B.Sc. New Ordinance (1907) (two subjects): Robert M. Allan, Charles J. G. Bourhill, George S. Brock, J. Falconer Brown, Ernest H. Cameron, John Drummond, Francis R. Fraser, B.A., Alexander Hood, John Hunter, Eric C. Lang, Robert S. Lawson, M.A., Emilius C. Mackay, M.A., Philip W. Maclagan, Donald J. M'Laren, Robert D. M. Macpherson, Duncan F. Macrae, Norman F. Mann, Horace M. Mills, Archibald A. Morison, Duncan M. Morison, Malcolm M. Morison, Montgomery P. Paton, William C. Paton, James F. Penman, A. Z. Philips, Charles K. Pole, Allan H. Porter, Nicholas Purcell, Alexander W. Rattrie, Thomas C. Ritchie, William Russell, Thomas R. Sandeman, Austin N. Smith, James R. Stott, James Taylor, and John J. Tough.

Third Professional Examination.—D. C. Adam, David Aiken, R. J. Allsopp, Alexander Archibald, Fergus Armstrong, Alice E. M. Babington, T. H. Balfour, A. E. C. Beausoleil, R. A. Bell, Eveline R. Benjamin, W. M. Biden, T. C. Borthwick, F. A. J. Brodziak, G. S. Brown, A. Ninian Bruce, B.Sc., P. J. de Bruijn, W. F. Buist, O. S. Bulloch, W. L. Burgess, B. N. Burjorjee, A. W. Burton, Sarah E. Buyers, J. Argyll Campbell, John Cathcart, G. L. Cawkwell, A. D. Child, H. A. Cookson, N. A. Coward, James Crocket, Lucy E. Davies, J. K. M. Dickie, I. D. Dickson, Adelaide A. Dresper, J. W. C. Moore, William Morrison, J. A. Mortimer,

race, in the self-reliance which enables one to assert full rights, and in the capacity to maintain the struggle for subsistence. This decision will have an immediate and powerful influence in promoting legislation in the States restricting the hours of labour of women and children.

Eye-glasses for School Children.

The Committee on Elementary Education of New York reports that 36,000 children in the public schools of this city are suffering from visual defects that demand correction to enable these children to profit to the full by the opportunities for study furnished to them. This is 6 per cent. of the total number in the schools. The committee recommends the organisation of centres well equipped for the examination of school children whose sight is defective and the provision of eye-glasses made to prescription; the appointment by the Department of Health of 30 ophthalmologists to examine all the pupils of the public schools referred to them; and, finally, the appointment of an advisory body consisting of five members.

Commission on Problems of Nutrition.

The University of Illinois is about to appoint a commission for the purpose of conducting experiments on the effect on the consumer of the preservatives in common use in food-stuffs, especially meats. The work will be done under the direction of Professor Grindly of the department of physiological chemistry of the University. Associated with him will be Professor Chittenden of Yale College, Professor Abel of Johns Hopkins University, and Professor Mathews of the University of Chicago. This investigation is encouraged, and in part supported, by the beef packing houses of Chicago. The commission is composed of professors of physiological chemistry of wide reputation as accurate and trustworthy authorities in their field of practical work.

Serum Treatment of Cerebro-spinal Meningitis.

The medical director of the Rockefeller Institute for Medical Research, Dr. Simon Flexner, has recently made public the experiments by which the serum was finally obtained and the results which have thus far attended its use. The meningococcus was found to have many peculiarities. Its effects on guinea-pigs were not like those on man; experiments with goats only occasionally succeeded; the lesions in monkeys resemble those in man both macroscopically and microscopically, but in monkeys there is more involvement of the central nervous system. Encouraged by the results obtained by these tests the experimenters began to immunise a horse, and after eight months this serum was tried on man. At first the dose was small, 5 cubic centimetres; later it was increased to 10 cubic centimetres and 15 cubic centimetres, and then larger doses were given. The injection was always made directly into the spinal canal. In the last epidemic of cerebro-spinal meningitis in New York there were 5000 cases, with a mortality of 70 per cent. The first trial of the new serum was in an epidemic in Ohio, where it was used in 40 cases, with 29 recoveries and 11 deaths—a mortality of 27·5 per cent. It has since been used in 17 cases in New York, with 12 recoveries and five deaths; 20 cases in Boston, with 17 recoveries and three deaths; 15 cases in Philadelphia, with nine recoveries and six deaths; three cases in Baltimore, with two recoveries and one death; 30 cases in Belfast, with 22 recoveries and eight deaths; and five cases in other places, with four recoveries and one death. The total of all reported cases up to the present time is 130 treated with the serum, of which 95 recovered and 35 died—a mortality of 27·5 per cent.

April 21st.

LONDON HOSPITAL MEDICAL COLLEGE: UNIVERSITY OF LONDON.—Mr. G. P. Mudge will continue his course of five lectures on Mendelian Inheritance on Wednesdays, May 6th and 13th at 4.30 P.M. The first lecture will deal with the Mendelian principles; Mendelian inheritance in animals and plants. The second lecture will deal with Mendelian inheritance in man in regard to both normal and pathological characters; eye-colour, brachydactyly, tylosis palmaris et plantaris, epidermolysis bullosa, curly hair, hetero-chromia of iris, diabetes insipidus, congenital stationary night-blindness (Nettleship's case), congenital cataract, musical sense, albinoism, Daltonism, insanity, and tuberculosis; the possible nature of sex-limited diseases in man, its analogous manifestation in lower animals. These lectures, which are free to all students of the University, will be given in the physiological theatre.

Obituary.

PROFESSOR LEOPOLD VON SCHRÖTTER.

ON April 22nd the medical profession of Vienna and the many foreign medical men visiting the city were greatly startled by the announcement of the tragically sudden death of Professor Leopold von Schrötter, Ritter von Kristelli. After having completed his seventieth year Professor von Schrötter, who was director of the third clinic for internal medicine in the University of Vienna, ought to have resigned this post but the Senate of the University granted him another year, the so-called honorary year of lecturing, which would have terminated next July. On the opening of the first International Congress of Rhinology and Laryngology, which was held in Vienna from April 21st to 25th, and of which he was the honorary president and the moving spirit, he delivered a magnificent address on the two founders of laryngology, Dr. Türck and Dr. Czermak, at midday, and invited about 40 of the most eminent of the foreign visitors to spend the evening at his house. With them he engaged in animated conversation until midnight when he retired. An hour later his son happening to enter the bedroom found that his father was dead. The deceased suffered from sclerosis of the coronary arteries and an attack of angina pectoris had terminated his life. He had been ailing a little for some time but no one, himself included, had felt any alarm as the symptoms were very slight. Leopold von Schrötter was a son of a man distinguished in science, Anton von Schrötter, and was a native of Gratz where he was born in 1837. At a comparatively early age he took the degree of M.D. in the University of Vienna in 1861 and became assistant to Professor Skoda whose ill-health often made it necessary that his assistant should deliver the clinical lectures. He soon showed a special interest in laryngology and became *privat-docent* for this subject in 1867. On the death of Dr. Türck, the chief laryngologist of that time, von Schrötter succeeded in convincing the authorities that laryngology was a subject of sufficient importance to deserve a special clinic. When this clinic, which had only 16 beds, was established he was made director of it and thus he was the first and only professor of clinical laryngology in Europe. He soon received the additional appointment of professor of internal medicine and in this way had two clinics under his supervision until in the year 1890 a third clinic was created for him in the General Hospital, where he had both beds for laryngological and medical patients and an out-patient department as well. The laryngological clinic of 16 beds was given to Dr. Stoerk. Professor von Schrötter was without question the pioneer of modern laryngology and its independent position is largely due to his influence. The treatment of stenosis of the larynx, the diagnosis of laryngeal paralyses, and the relations between various diseases and those of the throat were among the principal subjects at which he worked. He was also the first to perform an intra-laryngeal operation, cocaine being the anæsthetic selected. It is therefore not surprising that most of the well-known laryngologists of the present day have been his pupils. His lectures were attended by a multitude of foreign physicians and surgeons and his private practice was enormous. His fame increased when, in 1887, he was called in consultation with Sir Morell Mackenzie to the then Crown Prince Frederick of Germany. He was the founder of the Vienna Laryngological Society and was co-editor of several monthly and weekly laryngological journals. Professor von Schrötter was an energetic, quick worker; his ideas were mostly sound and he knew how to give them vivid expression. He threw himself into the movement for establishing sanatoriums for the treatment of tuberculosis and he persevered until a model institution of this kind—Alland, the first in Austria—was erected. As a physician and clinical teacher he was much esteemed alike by patients and students. The latter had a trustworthy friend in him, and in order to bring them into contact with the patients he always required his students to spend their afternoons in the wards, accompanying him on his rounds. His lectures on Diseases of the Chest were masterpieces of their kind. Heart diseases, mediastinal changes, and in recent years the use of the x rays in the examination of the chest were his favourite subjects in this department of medicine. His manner was at all times cheerful and he had an unusual power of specially designed for the purpose and which is further admirably situated and in close proximity to the residences of all the medical men. So far no solution of the difficulty has been found, though it cannot be believed but that one agreeable to all parties exists. It is sincerely to be regretted that a gift given in circumstances such as the use of this hospital was given and, moreover, given for the use of those who are not in a position to provide all that may be necessary to insure their recovery from serious illness is threatened with withdrawal simply because of the existence of some little difficulty which if approached in the true spirit could be got over immediately. Arbitration has been eminently successful quite recently in far more difficult and far more vital matters.

ROYAL SOCIETY OF MEDICINE (ELECTRO-THERAPEUTIC SECTION).—The ordinary monthly meeting of the section will be held in the rooms of the Royal Philosophical Society, 207, Bath-street, Glasgow, on Friday, May 22nd, at 8.30 P.M. Mr. William Deane Butcher, President of the Section, will occupy the chair. The following papers will be read: Interrupted Currents for Electrical Testing and Treatment, by Dr. H. Lewis Jones; Some Reflections Based upon the Work done in the Electrical Department of the Royal Infirmary, Edinburgh, by Dr. Dawson Turner; and Ionic Medication in the Treatment of Some Obstinate Cases of Pelvic Disease in Women, by Dr. Samuel Sloan. An exhibition of electrical apparatus will be held in the same place from 3 P.M. to 10.30 P.M. Light refreshments will be provided free of cost to visitors. The meeting and exhibition will be open to all duly qualified medical practitioners. As the attendance in the evening will probably be considerable it is requested that those who may find it convenient to visit the exhibition in the afternoon will do so.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—On April 15th Mr. A. H. Evans, M.R.C.S. Eng., L.S.A., was presented with a handsomely chased and inscribed silver cake-dish on behalf of over 100 patients of the Sutton Coldfield Medical Dispensary. Mr. Evans is retiring from active work in connexion with the institution.—On April 24th at a public meeting at Gilfach Goch, South Wales, Mr. David Naunton Morgan, F.R.C.S. Irel., L.R.C.P. Lond., was presented with an oil painting by Mr. J. M. Hemy and a grand piano was given to Mrs. Morgan. Recently the Fellowship of the Royal College of Surgeons has been conferred upon Mr. Morgan, and this was taken as an opportunity for making the presentation in order to show the respect and esteem felt for him by the residents of the district.—At St. Columb (Cornwall) on April 18th Mr. John C. Mackay, M.D. St. And., L.R.C.P., L.R.C.S. Edin., J.P., was presented with a silver tea-tray, suitably inscribed, a silver tea service, and a silver rose-bowl. The present was accompanied with a bound volume containing an illuminated address and the signatures of 381 subscribers. The presentation was made by Mr. A. C. Willyams, J.P., on behalf of the subscribers, as a mark of respect and esteem for Dr. Mackay who after practising at St. Columb for more than 25 years has been obliged, owing to failing health, to relinquish the active work of his profession.

THE PUBLIC PURSE AND DEFECTIVE SCHOOL CHILDREN.—The Board of Education in a letter to the West Sussex Education Committee has sanctioned the spending of public money to meet the cost of treating children in elementary schools who are suffering from physical defects. The Board was appealed to owing to the alarming state of affairs which has arisen from the inspection of children at schools in the Horsham district of Sussex, where of 1315 children examined no fewer than 40 per cent. were found defective, and nearly one-half of these required an operation either for enlarged tonsils or adenoids. At the meeting of the Horsham school managers on April 15th it was stated that in the town of Horsham alone there were 60 cases of adenoids urgently requiring operations, 54 cases being very serious indeed. The difficulty in dealing with so many children can be seen at once, the more so as in the majority of the cases the necessary operations cannot be performed at the parents' homes. But the difficulty has been surmounted, thanks to the sanction of the Board of Education and the loan of a cottage by one who is interested in the work. This cottage will be the temporary hospital and the nurses and necessaries will be supplied from the cottage hospital, the education authority subscribing to the cottage hospital such a sum as the hospital committee thinks appropriate. This arrangement, it was stated, entirely met with the approval of the authorities at Whitehall, but education authorities will have to keep a close watch upon the use of the public purse in this matter or they will be greatly imposed upon by parents. Every care must be taken to see that the parental obligation is insisted upon wherever possible, or parents will be found accepting free medical advice and help when really they are in a position to pay for it, or at least to pay something towards it. The serious extent to which this new call upon the public purse may develop is shown by the very large number of defective children in a healthy rural district. What of the cities and large urban areas?

MEMORIAL TO THE LATE MR. WILLIAM VAN PRAAGH.—The services to the deaf and dumb rendered by the late Mr. William Van Praagh have been acknowledged by the association for their oral instruction. Mr. Van Praagh, who died last year, was director of the school and training college connected with it for 37 years and was a leading exponent of the association's excellent method. A mural tablet in his memory was unveiled on April 27th at the school of the association by the Rev. C. H. Parey, acting on behalf of Mr. Leopold de Rothschild. There were over 100 subscribers to the memorial.

MEDICAL MAGISTRATES.—The names of Mr. Harry Davis, senior, M.D. St. And., M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., of Callington; Mr. John C. Mackay, M.D. St. And., L.R.C.P., L.R.C.S. Edin., of St. Columb; and Mr. Robert Garven Nesbitt, L.R.C.P., L.R.C.S. Irel., of St. Just, have been placed on the commission of the peace for the county of Cornwall. Mr. Henry Gervis, M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., has been placed on the commission of the peace for Brighton. Dr. Gervis filled the mayoral chair in 1906–07 and is at the present time the deputy mayor.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of this society was held at 6, Catherine-street, Strand, London, W.C., on April 15th. There were present Dr. F. de Havilland-Hall (in the chair), Dr. W. Knowsley Sibley, Mr. F. S. Edwards, Mr. J. Brindley James, Mr. J. F. Colyer, Dr. F. S. Palmer, Dr. St. Clair B. Shadwell, Dr. M. Greenwood, Mr. Edward Bartlett, and Dr. J. B. Ball. The amount of sickness pay disbursed by the society in the first three months of this year has been somewhat augmented by the epidemic of influenza, but the number of claims from this source now being received is not great and the illnesses are for the most part of short duration. The number of new members obtained this year is larger than in any previous similar period and has so far beaten the record figures of last year. The annual report to be presented to the members on May 21st will show that during the year 1907 the society has largely grown, both in members and in financial strength. Prospectuses and all further particulars can be obtained on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

TRINITY COLLEGE, DUBLIN: POST-GRADUATE CLASSES.—Trinity College has now issued a complete syllabus of post-graduate classes in connexion with the medical school for 1908. In addition to the summer course held in the month of June it has been decided to hold an autumn course which will begin on Sept. 21st and end on Oct. 10th. The subjects and lecturers respectively chosen are:—Medicine: Dr. Henry T. Bewley and Dr. A. R. Parsons. Surgery: Mr. Thomas E. Gordon and Professor Edward H. Taylor. Gynæcology: Mr. E. Hastings Tweedy. Diseases of the Eye: Sir Henry R. Swanzy. Diseases of the Throat, Nose, and Ear: Mr. Robert H. Woods. Diseases of the Skin: Dr. Wallace Beatty. Pathology: Dr. Alexander O'Sullivan. Anatomy: Professor A. Francis Dixon. Physiology: Professor W. H. Thompson. X Ray work: Dr. William S. Haughton. Cystoscopy: Mr. K. E. L. G. Gunn. From the time table it will be seen that work will begin at 8.30 A.M. and will be continued through the day, with an interval for lunch, till 5.30 P.M. Through the kindness of the Provost it will be possible for a certain number of the class to reside in college rooms and to dine on commons at a moderate cost. This opportunity of pleasant social intercourse after the day's work is done has been highly prized in the past. The number of rooms available, however, is limited and consequently early application for them is desirable. Further details will be found in our advertising columns in a recent issue and a complete syllabus can be obtained from the honorary secretary, 27, Lower Fitzwilliam-street, Dublin.

J. M. Moyes, C. C. Murray, R. M. Nicholson, F. H. Noronha, James Oag, M.A., John Renwick, D. G. Robertson (with distinction), W. S. Robertson, D. M. Ross, William Ross, M.A., R. P. Rosser, A. C. Russell, C. M. Schaffter, Jessie A. Scott, J. J. M. Shaw, M.A., J. C. Simpson, Kerr Simpson, G. H. Sinclair, J. D. Skinner, H. F. Smith, B.A., J. G. Smyth, James Sprent, B.Sc., William Stevenson, William Stewart, C. P. A. Stranaghan, James Swan, A. L. Taylor, H. W. Teague, J. A. Thompson, L. R. Thomson, W. S. Thomson, N. J. Watt, J. P. Whetter, Seymour Williams, John Wilson, J. D. Wilson (with distinction), and Margaret C. Young.

Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.—At the recent aexminations of the board of the Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow the following candidates passed their respective examinations:—

Five Years' Course.

First Examination.—Arthur Lloyd Edwards, Penygroes; James Alfred Frost, Glenbrook; George Anthony Macvea, Whithorn; Cyril Scotter Owen, Hale, Cheshire; William Shorten, Timoleague; and Valentine Hutchinson Wardle, Bishop Auckland.

Second Examination.—John Paxton, Norham-on-Tweed; and Hugh Francis Williams, Llanfyllin.

Third Examination.—Conrad James Arthur, Grenada, W.I.; Herbert Christian Bankole-Bright, West Africa; Denis Cogan, Cork; James Denis Collins, Cork; John Alexander Irwin, Donegal; Angus Cameron Livingston, Glasgow; Patrick James Taaffe, Liverpool; and Frank Walter White, Gosforth.

Final Examination.—Ishwar Das, Punjab; Charles James Campbell Faill, Edinburgh; William Richard Griffith, Bettws Abele; Maurice Edward Kayton, Bagdad; James William Muir Hunter, Nottingham; Les Singarayen Machado, Ceylon; John Moncrieff Muir, Kilmarnock; Manec B. Patel, Bombay; Sécossène Piarroux, Mauritius; Patrick Reid, Carlow; and Bildey Singh, Lahore.

Foreign University Intelligence.—*Berlin:* Dr. Georg Lockemann of Leipsic has been appointed to the charge of the Chemical Department of the Institute for Infectious Diseases in succession to Dr. Proskauer.—*Breslau:* Dr. Danielsen has been appointed *Oberarzt* of the Surgical Clinic in succession to Professor Anschutz who goes to Kiel.—*Copenhagen:* Dr. Hartmann has been recognised as *privat-docent* of Gynæcology.—*Greifswald:* Dr. W. Lange, of the aural department of the Charité, Berlin, has been appointed Extraordinary Professor of Otology and Director of the Aural Policlinic, in succession to Dr. Wittmaack, who has gone to Jena.—*Halle:* Dr. Winternitz and Dr. Frese, *privat-docenten* of Medicine, have been granted the title of Professor.—*Lemberg:* Dr. E. Biernacki, *privat-docent* of Experimental Pathology, has been granted the title of Extraordinary Professor.

Far Eastern Association of Tropical Medicine.—A conference of medical men practising in the Far East was held in Manila on Feb. 27th to consider the advisability of establishing a society to further the knowledge of tropical medicine and to promote friendly international intercourse among those whose medical or scientific duties and interests bring them into close contact with the natives of these regions. The following gentlemen took part in the conference: Dr. N. Black (Singapore), Dr. F. W. Clark (Hong-Kong), Dr. Cheng (Canton), Dr. Dudley (Manila), Dr. R. T. Edwards (Siam), Dr. H. Fraser (Federated Malay States), Dr. Paul C. Freer (Manila), Dr. Garrison (United States Navy), Dr. Gurney (Philippine Constabulary), Dr. Hayward Hays (Siamese Navy), Dr. R D. Keith (Singapore), Dr. Kitajima (Japan), Dr. J. R. McDill (Manila), Dr. H. T. Marshall (Manila), Dr. W. E. Musgrave (Manila), Dr. Nichols (United States Army), Sir Allan Perry (Ceylon), Dr. Pond (Manila), Captain Ryley, R.A.M.C. (Hong-Kong), Dr. Saleeby (Manila), Dr. Tee Han Kee (Manila), and Dr. J. J. Vassal (Annam). It was unanimously decided to establish such a society and the articles of association and by-laws were duly adopted. The council of the association will consist of a representative from each component Government and a representative from each component medical organisation, and it is hoped that during the ensuing year the Governments of Japan, China, Hong-Kong, the Philippine Islands, Tonkin, Annam, Singapore, the Federated Malay States, Siam, Borneo, Java, Ceylon, and other Far Eastern States and Colonies will nominate representatives, and that each medical organisation or branch of such organisation will similarly nominate a representative to serve on the council of the association. It was further decided to organise a conference every two years, to be held in one or another of the above countries, the first conference to take place in Manila early in the year 1910, and Dr. Paul C. Freer, director of the Bureau of Science of the Philippine Islands, was elected as the first President of the association. At these conferences papers will be read, pathological and other scientific exhibits displayed, and the medical, sanitary, and other allied institutions and services of the country in which the meeting is held will be thrown open, so far as may be possible, and demonstrated to those attending the meeting. Each component country will be represented for business purposes by a secretary-treasurer and there will be a general secretary-treasurer for the association. Dr. Francis W. Clark, medical officer of health of the colony of Hong-Kong, was elected the first general secretary-treasurer. The subscription was fixed at 10*s.* a year. Dr. Clark's address for the next few months will be the Royal Societies Club, St. James's-street, London, S.W.

Donations and Bequests.—By the will of the late Mr. Stewart Clark of Linlithgow the following sums are left to charities: £5000 to the Royal Alexandra Infirmary, Paisley; £2000 to the Annie Clark Fund for Incurables, Paisley, and the Annie Clark Fund for Incurables, Larne; £1000 to the Gleniffer Home for Incurables, Paisley; £1000 to the Royal Victoria Eye Infirmary, Paisley; and £1000 to the Paisley Convalescent Home, West Kilbride.—By the will of Mr. Stephen Hamilton Thompson of Edgbaston, who left estate valued at £45,364 gross, with net personalty £23,712, the residue of his estate will be equally divided between the Birmingham and Midland Throat and Ear Hospital, the Queen's Hospital, Birmingham, the Royal Institution for the Instruction of Deaf and Dumb Children, and the General Institution for the Blind, Birmingham. But if each of these institutions would receive more than £2000 such excess is to be distributed by his trustees among such charitable institutions as they think best.—The late Mrs. F. Yarde of Exeter has bequeathed £1000 to the funds of the Royal Devon and Exeter Hospital, Exeter.

Evelina Hospital for Sick Children.—Presiding at the annual court of governors on April 22nd, Sir W. P. Treloar, Bart., in moving the adoption of the report, said it was a tribute to the work of the hospital that the trustees of King Edward's Hospital Fund had made a grant of £250 during the year, as against £100 in the previous year, and the authorities of the Fund had further shown their appreciation by making substantial grants to the new building. Moreover, the grant from the Hospital Sunday Fund had been increased from £180 to £270. In the course of the year a new wing had been opened which was now in full operation. Its total cost was £14,000. Many children were sent to convalescent homes at an annual cost of about £300, and in this connexion he hoped that the home for crippled children which he was engaged in establishing at Alton, and which he hoped would be opened in June or July, would be able to afford accommodation to patients of the Evelina and other such hospitals who needed medical treatment in the country. The report was adopted.

Corbridge Hospital.—Corbridge is a pretty residential village of some 2000 to 3000 inhabitants, situated on the banks of the Tyne, 17 miles west of Newcastle on the Carlisle railway line. Corbridge is the centre of a very large agricultural district and though now only a village, and in many respects much less important than the neighbouring market town of Hexham, it has in the past taken a very important share in the history of this part of the country, as is evidenced by the fact that immediately adjacent to the modern village are the remains of one of the largest Roman settlements in Britain. The village and district have for some years enjoyed the privilege of the use of a small cottage hospital erected in memory of the late Mr. H. S. Edwards of Byethorn by members of his family. The hospital has in the past been managed by Miss Edwards, with the assistance of a committee of ladies. Rumours of disagreement among the members of the committee have been circulated for some little time. The committee was lately strengthened by the addition of some male members but without avail. The differences of opinion in the committee became more acute and finally the whole of the members resigned, with the result that the hospital was closed some three months ago. Since then a new committee has been formed and various proposals have been made, including a suggestion that a piece of land should be acquired and a new hospital erected. It would seem improbable that this latter suggestion will meet with the approval of those who contribute to the maintenance of the hospital, seeing that there already exists a building which was

John Bale, Sons, and Danielsson, Limited, 83-91, Great Titchfield-street, London, W.

Heredity, Variation, and Genius. With Essay on Shakspeare: "Testimonied in his own Bringingsforth." An Address on Medicine: Present and Prospective. By Henry Maudsley, M.D. Price 5s. net.

Miller, Charles C., 70, State-street, Chicago.

Cosmetic Surgery. The Correction of Featural Imperfections. By Charles C. Miller, M.D. Second edition, enlarged. Price $1.50.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Benson, Christopher Richmond, M.R.C.S., L.S.A., has been appointed Medical Officer for the Bratton Clovelly District by the Okehampton (Devon) Board of Guardians.

Mill, G. Robertson, M.D. Edin., has been appointed Honorary Medical Officer to the Birkenhead Maternity Hospital.

Reese, David William, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health by the Warmley (Gloucestershire) Rural District Council.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Army Medical Service.—Thirty Commissions.

Benenden Sanatorium.—Medical Superintendent. Salary £250 per annum, with board, lodging, and attendance.

Bloomsbury Dispensary.—Physician. Salary 100 guineas.

Bridgend, Glamorgan County Asylum.—Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, attendance, and washing.

Bristol General Hospital.—Assistant House Physician. Salary £80, with board, residence, &c.

Cardiff Infirmary.—House Physician for six months. Salary £30, with board, residence, and laundry.

Carlow District Asylum.—Resident Medical Superintendent. Salary £350 per annum and allowances.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Physician to Out-patients. Also Clinical Assistant.

Clinical Research Association.—Assistant Director of the Laboratory. Salary £250 per annum.

Derbyshire Royal Infirmary.—House Surgeon. Salary £100 per annum, with apartments, board, &c.

Dreadnought Hospital, *Greenwich*.—Assistant Physician; also Assistant Physician or Surgeon for Diseases of the Throat, Nose, and Ear.

Dumfries, Crichton Royal Institution.—Two Resident Clinical Physicians. Salary at rate of 50 guineas per annum, with board, rooms, and laundry.

Fermanagh County Hospital, Enniskillen.—House Surgeon.

Guildford, Royal Surrey County Hospital.—House Surgeon. Salary £100, with board, residence, and laundry.

Hôpital Français, 172, Shaftesbury-avenue, W.C.—Junior Resident Medical Officer, unmarried, for six months. Salary £50 per annum, with full board.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident House Physicians for six months. Salary £25.

Huddersfield Infirmary.—Junior House Surgeon. Salary £50 per annum, with board, residence, and washing.

Huddersfield Local Education Authority.—School Medical Officer. Salary £300 per annum.

Ipswich, East Suffolk and Ipswich Hospital.—Third House Surgeon. Salary £50 per annum.

Kettering and District General Hospital.—Resident Medical Officer, unmarried. Salary £80 per annum, with board, residence, &c.

Felix Asher, of Holy Trinity, Brighton, Arthur Jaffrey Hutchison, M.A., M.B., 84, Lansdowne-place, Hove, to Eve Muriel Lankester, elder daughter of Mr. and Mrs. Horace Eyre Haynes, 32, Brunswick-terrace, Hove.

DEATHS.

Bowen-Davies.—On April 24th, at Gorphwysfa, Exmouth, William Bowen-Davies, L.R.C.P., M.R.C.S., L.S.A., J.P., late of Brynarlais, Llandrindod Wells, aged 60 years.

Daglish.—On April 23rd, at New Romney, Kent, Richard Rothwell Daglish, J.P., Mayor of New Romney, aged 66 years (retired Practitioner).

Mull.—On April 18th, at Ventnor, Isle of Wight, William Ernest Mull, B.A. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., youngest son of the late William Mull, M.D., Kirby Moorside, and Mrs. Mull, Scalby, Yorks.

Prangley.—On April 24th, at Tudor House, Anerley, Henry John Prangley, M.R.C.S., L.R.C.P., aged 50 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Death of Sir Henry Campbell-Bannerman.

PROFOUND regret is felt in Parliamentary circles at the death of the late Prime Minister, Sir HENRY CAMPBELL-BANNERMAN, which came so close on his resignation of office. Expression was given to this feeling on Monday, the day of the memorial service in Westminster Abbey, curiously enough also the date on which the House of Commons reassembled after the Easter recess. All controversial business was laid aside for the day as a mark of respect to the dead statesman. In dignified and eloquent language the new Prime Minister, Mr. ASQUITH, paid a fitting tribute to his predecessor, to his capacity in affairs of State, to his urbanity and charm of manner, his kindliness of disposition, his power of leadership. Mr. AKERS-DOUGLAS, in the absence of Mr. BALFOUR, gave expression to the generous sentiments of the Opposition. Mr. A. HENDERSON spoke for the Labour Party, Mr. T. P. O'CONNOR for the Nationalists, and Sir ALFRED THOMAS for the Welsh Members. The House then adjourned.

New-born Children (Protection) Bill.

Lord ROBERT CECIL has introduced into the House of Commons a Bill "to provide for the better protection of the lives of new-born children."

Scottish Vital Statistics.

During the Easter recess the report of the Registrar-General on the births, deaths, and marriages in Scotland during 1907 was published. The population of the country was estimated at 4,776,053. The birth-rate for the year, 26·97, is the lowest yet recorded in Scotland. In 1906 it was 27 9 per 1000 of the estimated population. The death-rate for the year was 16·18 per 1000.

HOUSE OF COMMONS.

TUESDAY, APRIL 28TH.

Medical Women as Medical Referees.

Mr. STANGER asked the Secretary of State for the Home Department whether he could give any estimate of the number of female workpeople, including domestic servants, who, in the United Kingdom, came under the provisions of the Workmen's Compensation Act, 1906; and whether he had placed, or was intending to place, any duly qualified female medical practitioners on the lists of persons to act as medical referees or medical assessors under that Act, so that female workpeople making claims under the Act might, where the county court judge allowed it, have the services of a female medical practitioner.—Mr. GLADSTONE replied: It is estimated that the number of female employees who come within the Act is approximately three millions. The question of appointing medical women to act as medical referees in cases where women are concerned is one of much administrative difficulty. It has been carefully considered, but I have not seen my way to make any such appointments at present. There were only two references to medical referees in women's cases during the year 1907. I should always be ready to consider an application by a county court judge for the *ad hoc* appointment of a medical woman to act as referee in a particular case where the circumstances were exceptional.

The Dairies, Cowsheds, and Milkshops (Ireland) Order.

Mr. HUGH BARRIE asked the Chief Secretary to the Lord Lieutenant of Ireland whether, having regard to the fact that the Dairies, Cowsheds, and Milkshops (Ireland) Order, 1908, was compulsory, and that its provisions were for the purpose of improving the general health of the community and assisting to stamp out the disease of tuberculosis, he would urge upon the Government the necessity of contributing one-half of the cost of giving effect to the Order.—Mr. BIRRELL sent the following written reply: The answer is in the negative. There is no reason why the Government should contribute one-half of the cost of giving effect to the Order in question, that would not equally apply to the case of every Order which aims at improving the general health of the community.

A Standard for Food Preservatives.

Mr. FIELD asked the President of the Local Government Board whether, owing to the absence of any standard for preservatives in food and the consequent confusion prevailing in the public mind, he would be prepared to incorporate in the regulations he was now drafting under the powers conferred upon him by the Public Health (Regulation of Foods) Act, 1907, a clause fixing such standard, and thereby give practical effect to the recommendations of the Departmental Committee of 1900.—Mr. BURNS (by written answer) replied: In view of the importance of public health and trade interests concerned regulations dealing with preservatives in food generally could not be made without considerable preliminary inquiry or without supplementing the investigations of the Departmental Committee in various directions. In these circumstances it has not been found practicable to include regulations on this subject in the series now in preparation, but I have not lost sight of the matter and have already directed inquiries to be made with regard to the present position of preservatives in certain foodstuffs.

WEDNESDAY, APRIL 29TH.

The Royal College of Surgeons in Ireland.

Sir WILLIAM COLLINS asked the Chief Secretary to the Lord Lieutenant of Ireland whether he had considered a memorial from the Royal College of Surgeons in Ireland praying that that body might become a constituent college in the new university to be established in Dublin; and whether he would be prepared to advise the inclusion of that College within the university.—Mr. T. W. RUSSELL (on behalf of Mr. BIRRELL) replied: It is not intended to make the Royal College of Surgeons in Ireland a constituent College of the proposed new university in Dublin.

Sir WILLIAM COLLINS asked whether further representations on the subject would be considered.—Mr. T. W. RUSSELL replied that he had no doubt that any representations coming from the College would receive due consideration.

BOOKS, ETC., RECEIVED.

APPLETON, SIDNEY, London.

Medical Gynecology. By Howard A. Kelly, A.B., M.D., LL.D., F.R.C.S. (Hon. Edinb.), Professor of Gynecological Surgery in the Johns Hopkins University, and Gynecologist to the Johns Hopkins Hospital, Baltimore. Price 25s. net.

At the Royal Eye Hospital (2 p.m.), the Royal London Ophthalmic (10 a.m.), the Royal Westminster Ophthalmic (1.30 p.m.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of The Lancet should be addressed *exclusively* "To the Editor," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of The Lancet *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of The Lancet at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach The Lancet Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to The Lancet Offices.

Subscribers, by sending their subscriptions direct to The Lancet Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The Colonial and Foreign Edition (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from The Lancet Offices or from Agents, are:—

For the United Kingdom.		To the Colonies and Abroad.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given above. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of The Lancet necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of The Lancet have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—The Manager, The Lancet Offices, 423, Strand, London, England.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Westminster Gazette, Glasgow Evening Times, Aberdeen Evening Express, Bristol Mercury, South Wales Echo, Manchester Chronicle, Aberdeen Journal, Lincolnshire Echo, Sunderland Echo, South Wales Daily News, Midland Weekly News, Law Times, Yorkshire Telegraph, Yorkshire Post, South Leeds Daily News, Somerset Weekly Gazette, Pall Mall Gazette, &c.*

Notes, Short Comments, and Answers to Correspondents.

THE NEEDS OF LONDON MEDICAL STUDENTS.

Mr. F. W. Collingwood has forwarded to us a pamphlet which he tells us will be circulated amongst London medical students at the commencement of the coming summer session. It rehearses the position of the Conjoint Diplomate with regard to his disability to assume the title of "Doctor" after passing examinations similar to those which at other centres would have entitled him to the designation of "M.D." The opinions on the matter which have been expressed by Sir W. H. Allchin, Professor W. Osler, and the Ethical Committee of the British Medical Association are quoted, and the circular concludes thus:—"Therefore, urge your teachers to move in this matter, which so materially affects your future welfare and position as practitioners of medicine, and petition the Minister of Education, Whitehall, S.W., on the subject, so that your grievances may be fully known and attended to by any forthcoming commission which will probably sit and report upon the whole question of medical education in London."

LONGEVITY AT BRIGHTON.

To the Editor of THE LANCET.

SIR,—One or two mistakes appear in my letter which you published in your issue of April 18th, p. 1188, and for the sake of accuracy I should be obliged if you will kindly allow me to correct them. Charles Green's ("Old Evergreen") age was 107; Captain W. Skipwith (not "Sitwell"). As a student of everything appertaining to Brighton I recently came upon this note in a short history of Brighton written by Anthony Relhan, M.D., in 1761, and this may perhaps account for the remarkable purity and invigorating properties of the Brighton air:—

> Chalky ground has little or no perspiration and therefore must be extremely healthy. The ground of this soil does not crack nor the grass burn so soon as in other soils. This is perhaps partly owing to the reflecting power of the chalk, partly to the declivity of the hills and yet in wet weather it sooner grows dry so that you may immediately ride after heavy rains without the least inconveniency. Hence it follows that in this soil there can be no marshy swampy ground excepting in such places as border on rivers. Now as the nearest river to this town is really six miles distant and as this is a circumstance peculiar to itself, no other maritime town in England being equally remote from one, I may venture to affirm that the soil here is extremely dry and that the air of this place must be proportionably pure.

I am, Sir, yours faithfully,
J. P. BACON-PHILLIPS.
Crowhurst Rectory, Sussex, April 20th, 1908.

PS.—Mrs. Taylor, widow of the late Mr. Peter Taylor, M.P., died at Brighton the week before last in her ninety-eighth year. She had lived at Brighton for 17 years.—J. P. B.-P.

AN INTERESTING PROSECUTION.

A MAN named Mortimer has been committed for trial at Swansea and has since been taken before the magistrates at Exeter and remanded, complaints having also been made with regard to him at Abergavenny. The charges against him are based upon representations said to have been made by him that he could cure various forms of disease, and it was alleged by witnesses at Exeter that he had obtained from them sums of £8 15*s.* and £4 10*s.* by statements with regard to his power to heal. We do not propose to say more upon the subject while the cases involved are *sub judice*, but the further proceedings will be watched by members of the medical profession with interest, and whatever may be their result with regard to Mortimer they should have some bearing upon the claims to heal made by others who have no qualification to do so and upon the circumstances in which criminal proceedings may be taken against such persons with a prospect of success.

BAGNOLES DE L'ORNE.

To the Editor of THE LANCET.

SIR,—I should be obliged if, in your "Answers to Correspondents," you or readers of THE LANCET would inform me as to the suitability of "Bagnoles de l'Orne" in Brittany for treatment of varicose veins in the leg and more especially for recurrent attacks of phlebitis, probably gouty in nature. Also as to the best time to go there and the length of treatment usually given.

I am, Sir, yours faithfully,
DYED GALLINA.
April 27th, 1908.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

WEDNESDAY.

NEUROLOGICAL SECTION (Hon Secretaries—Leonard G. Guthrie, E. Farquhar Buzzard): at 8.30 P.M.

Papers:

Sir William Gowers, F.R.S: The Mechanism of Nystagmus.

Dr. E. Farquhar Buzzard: A Note on the Occurrence of Muscle Spindles in Ocular Muscles.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries—Raymond Johnson, A. E. Garrod): at 8.30 P.M.

Cases:

Mr. Watson Cheyne: Spontaneous Disappearance of Recurrent Carcinoma of Breast.

Sir Thomas Barlow and Mr. C. A. Ballance: Suture of the Brachial Plexus for Birth-palsy.

Dr. Purves Stewart: Meningo-cortical Lesion illustrating Astereognosis.

Dr. J. Barnes Burt: Three Cases of Gout showing Destructive Changes in Bone.

Mr. C. H. Fagge: (1) A Case in which for Recurrent Sarcoma Parts of the Femoral Artery and Vein were Excised; (2) A Case of Aneurysm of the Common Femoral Artery, Excision of Aneurysm and of the Common Femoral Vein.

Dr. G. A. Sutherland: Scleroderma.

Mr. Albert Carless: Multiple Diffuse Lipomata.

Mr. P. Maynard Heath: Caries of Spine with Clubbing of Fingers and Toes.

The Cases will be in attendance at 8 p.m.

Short Papers:

Mr. C. A. Ballance: A Case of Arterio-venous Anastomosis for Senile Gangrene.

Dr. Norman Dalton: A Case of Leucoderma dying with Symptoms of Addison's Disease.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.—At the next Meeting, to be held on May 14th, a paper by Dr. R. H. Paramore on "The Supports of the Female Pelvic Viscera" will form the basis of a discussion on this subject. The paper will not be read in full, but will be printed beforehand and copies may be obtained on application to the Honorary Secretaries, 20, Hanover-square.

ELECTRO-THERAPEUTICAL SECTION.—The next meeting take place on May 22nd in the Rooms of the Royal Philosophi Society, Glasgow. Members who wish to attend and who des to avail themselves of local hospitality should communic with Dr. Reginald Morton, honorary secretary, in order t the necessary arrangements may be made in good time.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wale General Hospital, Tottenham, N.

THURSDAY.—4.15 p.m., Clinical Cases.

HARVEIAN SOCIETY OF LONDON, Paddington Green Childre Hospital.

THURSDAY.—8.30 P.M., Clinical Evening.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDO 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Mr. E. E. Henderson, Mr. E. Green, Mr. Hailes, and Mr. J. H. Tomlinson: Card Specimens. Dr. Fergus: Ptosis Operations. Mr. E. Clarke and Sir A. Wrigh Tubercle of the Choroid cured by Tuberculin. Mr. E. Clarl and Mr. S. Mayou: Tubercle of the Iris cured by Tubercul Mr. P. E. H. Adams: An Epidemic of Contagious Conjun tivitis due to the Pneumococcus. Dr. G. Mackay: (1) A Ca of Arterio-venous Aneurysm treated by Ligature of the Commo Carotid; (2) A Case of Phlyctenular Keratitis and Pustul Episcleritis treated by Antistaphylococcic Injections.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN, 1 Chandos street, Cavendish-square, W.

FRIDAY.—5 P.M., Dr. O. K. Williamson, Dr. Carpenter, Dr. F Parkinson, Mr. Lett, Mr. R. Howard, and others: Cases an Specimens. Dr. W. Ewart: The Empty Bronchus Treatmen by Posture in the Bronchiectasis of Children.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 2 Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Little: Clinique (Skin). 5.15 P.M., Lecture:—Sir William Collins: Some Tendencies in Moder Medicine.

TUESDAY.—4 P.M., Dr. J. Taylor: Clinique (Medical). 5.15 P.M., Lecture:—Dr. H. Campbell: Jacksonian Epilepsy.

WEDNESDAY.—4 P.M., Mr. J. Clarke: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. E. T. Collins: Convergent Strabismus.

THURSDAY.—4 P.M., Mr. Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Sir Malcolm Morris: Pruritus Ani.

FRIDAY.—4 P.M., Mr. S. Stephenson: Clinique (Eye).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2.15 P.M., Sir Dyce Duckworth: Medicine. 2.30 P.M., Operations. 3.15 P.M., Mr. W. Turner: Surgery. 4 P.M., Mr. L. A. Lawrence: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. Special Lecture:—2.15 P.M., Sir Dyce Duckworth: Hæmatemesis.

The Goulstonian Lectures

ON

THE INFLUENCE OF PREGNANCY UPON CERTAIN MEDICAL DISEASES, AND OF CERTAIN MEDICAL DISEASES UPON PREGNANCY.

Delivered before the Royal College of Physicians of London on March 17th, 19th, and 24th, 1908,

BY HERBERT FRENCH, M.A., M.D. OXON., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO GUY'S HOSPITAL.

LECTURE II.[1]

Delivered on March 19th.

OTHER SUPPURATIVE RENAL AFFECTIONS IN RELATION TO PREGNANCY.—TUBERCULOUS AND CALCULOUS DISEASES.

MR. PRESIDENT AND GENTLEMEN,—The pyelonephritis which pregnancy itself gives rise to having been discussed, there remain two other suppurative renal affections to be mentioned. These are the various degrees of kidney mischief that may be due to stone and to tuberculosis respectively. There is little evidence to show that pregnancy is itself liable to give rise to either of these, and in the case of a tuberculous kidney the patient is, as a rule, so invalided that pregnancy is but rarely to be found associated with it. There has been no case of pregnancy coincident with tuberculous kidney in Guy's Hospital in the last 20 years. With renal calculus, on the other hand, the symptoms may be in abeyance for longer or shorter periods and the patient is not necessarily such an invalid that pregnancy may not occur. The question will then arise as to what the effect upon the kidney is likely to be in such a case. It is clear that if a previously healthy woman may develop pyelonephritis during pregnancy, as described in the previous lecture, a woman who already has a lesion which also predisposes to pyuria must be in a position of increased danger when pregnancy occurs. On the other hand, the degree to which the kidney, or kidneys, may be already damaged by the calculi is so extremely variable that it is almost impossible to say what is going to happen when such a case comes under observation. If the calculus is a small one confined to the renal pelvis, the general substance of the kidney being but little affected, it is quite possible for the pregnancy to run its course without any trouble arising from it at all. If the stones are confined to one kidney and have led to its conversion into a hydronephrotic bag the other kidney may have hypertrophied by way of compensation, and the effect of pregnancy will be similar to that in cases where, after operation, only one kidney is left—a point to be mentioned again below.

Colic and hæmaturia may occur in either of these cases, just as they may in non-pregnant persons. Treatment should then be directed to the renal condition, and the probability is that the untoward symptoms will subside and that the pregnancy will run its natural course, as was the case in six out of seven patients in the hospital. On the other hand, a patient with a renal calculus that is already causing suppurative inflammation of the kidney is bound to be a source of grave anxiety to her medical attendant should she become pregnant, especially from the fifth month onwards, that is to say during the time when there is particular liability for the pregnancy itself to cause pyelonephritis. It is doubtless possible by keeping the patient at rest, by preventing constipation or diarrhœa, and by administering anti-pyuric remedies, to enable her to reach her full term of pregnancy; but there are cases in which the suppuration in the kidney will become worse, and the question will arise as to whether or not obstetric measures for terminating the pregnancy should be advised. One of the seven cases alluded to above proved fatal; it may probably be regarded as one in which pregnancy was the main cause of death by leading to a pyelonephritis upon the top of calculous disease. The following are brief details of the case:—

The patient was a young woman who had had pain in her right loin which in view of the subsequent events was doubtless due to a calculus. She was otherwise in excellent health. She married and remained well until she was five and a half months pregnant. She then began to suffer from aching pains across her loins and from repeated vomiting. There was no œdema but the urine was found to contain 5 parts per 1000 of albumin, with a fair number of renal tube casts, red corpuscles, and a considerable excess of leucocytes. Day by day the leucocytes in the urine became more numerous until they amounted to pus, and the quantity of pus rapidly increased until there was no doubt about there being a progressive suppurative nephritis. No tubercle bacilli were found in the deposit. The urea still amounted to 1·7 per cent., but the patient became steadily worse, vomiting on the slightest exertion and after all food. There was no pyrexia such as there nearly always is in cases of ordinary pyelonephritis of pregnancy and there were no rigors. The bladder became infected by acute cystitis and the question of recommending obstetric measures for emptying the uterus had arisen, when spontaneous delivery of a living female child occurred at the seventh month. The patient's general condition improved for three days afterwards, though no day passed without the occurrence of vomiting. The latter then increased in severity; drowsiness with muttering delirium and hallucinations set in, with incontinence of urine; and on the fifth day after labour the patient became comatose and died without convulsions.

At the necropsy the only abnormal organs were the kidneys and the bladder. The uterus was perfectly healthy. Both kidneys were in a state of pyonephrosis, with secondary suppurative pyelonephritis, and in the pelvis of each there were numerous irregular calculi of oxalate of lime coated with white phosphates. The ureters were but slightly dilated. The bladder was in a condition of acute cystitis without ulceration.

Apparently the sequence of events had been: renal calculi, hydronephroses, pregnancy, microbial infection of the kidneys, pyonephroses, suppurative pyelonephritis, cystitis, uræmia, death. Unfortunately no exhaustive bacteriological examinations of the urine were made. One would not be surprised, in view of what has been already said in connexion with the pyelonephritis of pregnancy, if the micro-organism had been the bacillus coli communis in pure culture. This is a point for investigation in future cases.

NON-SUPPURATIVE RENAL AFFECTIONS IN RELATION TO PREGNANCY.

We may now pass on to consider the non-suppurative lesions of the kidney in their relation to pregnancy, and although these constitute a very big subject, and one which might easily occupy many lectures, it will be best to touch only upon a few points of it here because there is already a great deal of literature upon the matter, much of which is easily accessible to all.

There is still a good deal of discrepancy in the views held by different observers as to the nature of the lesions in question, for whereas some pathologists describe them as inflammatory others insist that they are not so but are rather acute toxic degenerations of the renal cells.

Clinical groups.—Clinically there are three quite distinct groups of cases which some would distinguish from one another in kind as well as in type. 1. The cases in which renal mischief of the nature of Bright's disease has been known to exist previously to pregnancy. 2. The cases in which, previously to pregnancy, the urine was perfectly healthy and no previous attack of Bright's disease had occurred; but in whom during pregnancy, and beginning, as a rule, at or before the middle of the pregnancy, puffiness of the ankles, back, and eyelids appears, the urine at the same time becoming less in quantity and containing albumin, renal tube casts, and possibly blood, in a way which closely simulates ordinary acute Bright's disease. For the sake of brevity these are referred to as the "œdema cases." 3. The cases in which the patient has seemed to be in perfect health until the later months of pregnancy, or even until immediately after labour, and then without much warning and usually with only slight evidences of œdema develops the well-known symptoms of puerperal eclampsia. It is not at all improbable that there is a fourth clinical variety of renal disease that has a relationship to pregnancy—namely, the granular contracted kidney. It is very difficult to prove or to disprove this, because even if a granular contracted kidney in a given case owes its inception to renal trouble arising during pregnancy the patient can still continue to live for many years without untoward symptoms, and by the time death occurs there will be nothing in the post-mortem examination to show either how long the renal mischief has been present or how this mischief first began.

Recurrent obstruction to ureters is a potent cause of renal fibrosis and it is conceivable that many successive pregnancies may lead to sclerosis of the kidneys without there having been any of the symptoms of acute Bright's disease. I have accumulated some evidence to show that not only pregnancy but also pathological affections of the pelvic organs, such as prolapse of the uterus, may lead to fibrotic kidneys, with hypertrophy of the left ventricle of the heart, and all the other changes that are usually associated with

---

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapst, Asnières, Paris.

that which is usually referred to as such is the fibrosis which results from former acute or subacute inflammation, the inflammation itself having ceased long since. A similar misapplication is frequent in regard to valvular heart disease: valves which are crippled as the result of former endocarditis are often spoken of as being the site of chronic endocarditis, when what is really meant is fibrosis from former endocarditis, all actual inflammation being now past. Scarlet fever may cause nephritis which, instead of either resolving completely or leading comparatively soon to a fatal result, may leave behind it a fibrosis. It is not this lesion which is at present under discussion but the acute or subacute lesions which are on all hands allowed the title scarlatinal nephritis.

The kidney which may be found post mortem in such cases is very variable in its naked-eye appearances. Sometimes it is a large red blood-dripping organ, without much blurring of the structural outlines; sometimes it is a large pale kidney, with lack of clear definition between cortex and medulla; more often it is a combination of these two types, a large organ variously mottled with pallid and with crimson streaks and blotches, the general effect being in the direction of redness in some, in the direction of pallor in others, whilst sometimes there is about an equal proportion of redness and of pallor in the mottling. Granted time between the onset of the inflammation and the time of the patient's death, a variable degree of contraction of the kidney will have resulted, with unevenness of the surface owing to irregularity in the distribution of the fibrosis, the colour varying here again between pallor on the one hand and redness on the other as much as it does in the large kidneys of the earlier stages of the disease.

The microscopical changes are equally variable. Confining attention mainly to the acuter stages, the most striking feature is the obstruction and distension of the tubes, which are stuffed with epithelium, granular débris of cells, and often blood and fibrin; to the more or less obliteration of their channels. Sometimes the fibrin is so abundant as to occupy most of the tubes to the exclusion of their epithelial lining. Often the epithelium of whole groups of tubules seems to have undergone a sort of coagulation necrosis, the line of demarcation between each cell and its neighbour being no longer visible, and the nuclei no longer taking the ordinary stains. In the more protracted cases the peri-glomerular and inter-tubular connective tissue shares in the inflammatory process, displaying hypernucleation and proliferation of the connective tissue cells. The degree to which small round-celled infiltration occurs is extremely variable. Sometimes it is almost entirely absent, sometimes it is very obvious, particularly around the glomeruli and in the cortex. The patient may not die until, although there is still actual inflammation present in some places, in others there has been time for fibrosis to have occurred. In short, both the macroscopic and the microscopic appearances of kidneys that are the seat of scarlatinal nephritis are extremely variable, though it can scarcely be said that the different appearances constitute intrinsically different kinds in the inflammation. If any broad rule can be laid down it would be that the sooner after the onset the patient dies the more will the appearances be those of a coagulation necrosis of the epithelium; the longer the patient lives, supposing always that the renal mischief does not entirely resolve, the more will be the connective tissue change, first that of hypernucleation, and finally that of fibrosis.

If the description that has been given of the acute and subacute changes in the non-suppurative renal diseases of pregnancy be now recalled, it will be found that these are extremely similar to those that occur in connexion with scarlet fever. If the scarlatinal changes are to be termed nephritis then those associated with pregnancy are surely nephritis too. There have been in Guy's Hospital of recent years four fatal cases of the œdema type and 15 fatal cases of the eclamptic type of renal trouble in pregnancy out of a total of 71 cases of the former and 51 cases of the latter. There is little need to recount the changes that were found at the necropsies, because there is little to add to the descriptions already given above. If the kidneys themselves or microscopical sections of them had been mixed up amongst a large number of different scarlatinal nephritis kidneys and their sections, it would have been next to impossible to have gone through them and sorted the pregnancy kidneys from the scarlatinal. Large red, large mottled, large pale, contracting red, contracting mottled, and contracting pale kidneys were all represented, with a predominance of the large mottled and large pale kidneys in the eclampsia cases and of the contracting kidneys in the œdema cases. There were great variations in the microscopical appearances in different cases also. Sometimes cloudy swelling or coagulation necrosis of the epithelial cells in the cortex was the main thing; sometimes even in the eclampsia cases there was hypernucleation of the connective tissue as well. In the œdema cases there was a variable degree of fibrosis, mature and immature, which occasionally reached an extreme degree even in kidneys that were not very obviously contracted. It would seem that every kind of change which may be found in scarlatinal nephritis may also be found in these kidney affections of pregnancy. I therefore range myself with those who regard these kidney changes in pregnancy as essentially similar in kind to those which may occur in scarlet fever, and I believe that there is no intrinsic difference, but only one of degree and acuteness, between the renal changes in eclampsia cases and those in cases where renal œdema is a prominent symptom less late in the pregnancy.

The Cause of Pregnancy Nephritis.

It is not possible to say precisely what is the cause of the nephritis in pregnancy. It is generally believed to be a toxin—that is to say, a poison of unknown nature—elaborated during pregnancy. To term the changes in these pregnancy kidneys "toxic" does not imply that they are intrinsically different from those of scarlatinal nephritis, where the precise cause, being equally unknown, is termed toxic too. There are doubtless many different substances which can cause similar inflammatory lesions in the kidneys. Pneumococci have been recovered from these organs in cases of acute non-suppurative nephritis associated with lobar pneumonia. Streptococci have been recovered in a similar way from some scarlatinal nephritic kidneys. Cantharides, turpentine, and oxalic acid can cause very similar renal changes. It is more than likely that in certain cases pregnancy gives rise to a poison of some kind which in turn is the cause of the nephritis.

Nothing is really known as to why in some cases eclampsia should be the prominent feature, whilst in others œdema is marked and eclampsia absent, and whilst in yet others both occur. The parallel with scarlet fever nephritis still holds good in this respect, however. There are cases of scarlatinal nephritis in which œdema in entirely absent, and uræmic symptoms are the first to attract attention; whilst there are other cases in which œdema is a marked feature without uræmia. There is an admirable paper upon the subject by Dr. F. M. Turner.[2]

Notwithstanding all the work that has been done upon uræmia its pathology is still unknown. Of late years attention has been directed less exclusively to the kidneys in the study of the subject, and there is some evidence to show that the liver as well as the kidneys may play an important part in the origin of uræmic or eclamptic symptoms. The liver is nearly always abnormal in these cases, the chief changes being cloudy swelling, fatty change, and acute necrosis of the hepatic cells. It would not be surprising if the liver condition had something to do with uræmia, seeing that, if jaundice were deducted from the later symptoms of acute yellow atrophy of the liver, the clinical picture of the latter would not be very unlike that of uræmia.

Before leaving the question of whether or not the renal lesion of eclampsia is really similar in kind to the renal lesion of the cases where general œdema is the main symptom, it may be of interest to note that four out of the 71 cases who were admitted for the œdema type of nephritis in association with pregnancy had suffered from typical acute eclampsia in a former pregnancy. Eclampsia is not so common that this can be a mere coincidence. If the same patient is liable to acute eclampsia in one pregnancy and then to the œdematous form of nephritis without eclampsia in a later one, it is very suggestive of there being a relationship in kind between these two clinical forms of renal disease. If these were cases in which the œdema type of nephritis had come first and then eclampsia in a later pregnancy the argument would not be so good, though there are cases of this kind too. The four cases referred to had never had symptoms of nephritis apart from pregnancy; their first symptoms of renal trouble were those of puerperal eclampsia towards the end of their first pregnancy. Recovery from this appeared to be complete, and in a subsequent pregnancy there was the nephritic type of œdema associated red granular kidney, even including cerebral hæmorrhage. The data, however, are not yet complete, so that it will be best to leave the red granular kidney out of the question now under discussion and to confine attention to the three different clinical types of renal disease mentioned above.

---

[2] Guy's Hospital Reports, vol. li.

First in regard to pregnancy arising in a patient known to have Bright's disease at the time conception occurred. It is so clear that pregnancy is apt to have a deleterious effect upon the kidneys that it is manifestly unwise for a girl or woman with existing nephritis to get married. If the urine already contains both albumin and renal tube casts, there is a great risk that pregnancy will make the condition far worse and accelerate the end. The surprising thing is that some patients known to have persistent Bright's disease before pregnancy sometimes live to bear many children, even in spite of exacerbations of their renal symptoms during pregnancy. Such cases are exceptional, no doubt, but on going through the hospital records one finds several of this kind. In one there had been all the signs of chronic tubal nephritis for 13 years, the patient had been married for eight years, she had borne five children, and bore a sixth alive at term in the hospital. This was not a case of recurrent acute nephritis but of persistence of both albuminuria and tube casts; it is the more remarkable in that, even without the additional strain of pregnancy, it is unusual for a patient with such a renal condition to survive so long. Such an exceptional case merely shows that both pregnancy and survival may occur in a case of chronic Bright's disease; it does not follow that medical advice should not be against marriage in other cases of the kind.

There now remain the two groups of cases in which the renal disease is directly attributable to pregnancy—namely, those who develop renal œdema in the middle months and those who develop eclampsia at the end. The fact that these two forms of renal disease are really attributable to the pregnancy is so well established that it needs no discussion. In the majority of the cases both albumin and renal tube casts disappear from the urine in a remarkable way when the pregnancy has terminated. Clinically, the two types are so different that many authorities regard them as absolutely distinct renal affections; and some hold that both these two forms, besides differing from one another, are also entirely different from those renal affections which arise from other causes and which are usually grouped together under the title acute or subacute Bright's disease. It is very probable that the question of whether these pregnancy kidneys are really forms of Bright's disease or not will remain a matter upon which there will always be differences of opinion. The extent to which opinions differ at present is well exemplified in Sir T. Clifford Allbutt's "System of Medicine," where the accounts given in different volumes by such authorities as Dr. G. E. Herman and Dr. W. Howship Dickinson respectively, are remarkably at variance. Speaking of the morbid anatomy and histology of the kidneys in the two types of disease under discussion, Dr. Herman says of the first—namely, that in which œdema of ankles and eyelids in the earlier months is the main symptom—which he calls the "chronic renal disease of pregnancy":—

> We know nothing of the morbid anatomy of this chronic disease, for it is not fatal. The morbid changes in the kidney can only be found out by examining the kidneys of a pregnant woman who, having the disease, died from some accidental cause, and I know of no such record. A few necropsies have been published, but the accounts are not harmonious, for the evident reason that the patients who died were suffering from forms of renal disease such as occur independently of pregnancy and not from that which depends upon pregnancy.

This does not seem to be altogether fair, for it is as much as to say: "The chronic renal disease of pregnancy is different from that of chronic tubal nephritis due to other causes; therefore, if at a necropsy made upon a patient dying pregnant, or recently pregnant, lesions resembling chronic tubal nephritis are found, the nephritis is not that which pregnancy causes." It appears to be an argument in a circle in which the conclusion that is drawn is also one of the premisses of the syllogism.

Dr. Howship Dickinson, on the other hand, writes very differently. He says:—

> The changes which occur in the kidney as consequences of pregnancy may be briefly indicated. They are the changes of heart disease and something more. To passive congestion is superadded an acute inflammation. In an early stage there is much hyperæmia, with obvious fulness of vessels, general redness, and some increase of size. In a case destined to further trouble, a somewhat peculiar form of diffuse nephritis succeeds; the tubes become loaded with epithelium which early takes on fatty change and imparts a yellowish colour, in streaks or otherwise, to the section. The fatty change is not limited to the epithelium, but may be somewhat general. The tubal change is accompanied or quickly followed by interstitial contractile growth, with consequent compression of the tubes, particularly near the surface, and superficial granulation. The condition is one of general nephritis, upon which granular contraction ensues with inordinate rapidity. So early does the contractile process become superadded to, or intermixed with, that of inflammatory swelling that the more bulky results of renal inflammation are excluded; the large white kidney does not, under these circumstances, present itself. The early access of inflammatory change would seem to imply that other causes are at work beside the mechanical, and that these are analogous to those to which other forms of nephritis have been traced. It has been suggested that the kidneys are irritated by some product of pregnancy, possibly an excrementitious result of fœtal nutrition. The conjunction of the two morbid agencies, the mechanical and the vital, may account for the greater activity of the disease as compared with the granular kidney of other origin. The puerperal kidney has a mixed nature; it is one of diffuse nephritis, upon which granular contraction is rapidly superimposed.

Referring now to the kidneys found at necropsies in cases of fatal puerperal eclampsia, Dr. Herman says:—

> Very different conditions of kidney have been found. A comparison of the different accounts that have been published shows that they may be divided into three groups. First, disease of the kidney such as may occur apart from pregnancy, ... such as lardaceous disease, hydronephrosis, or dilatation of the ureters and renal pelves. Secondly, in most cases there are changes in the kidneys which to the naked eye resemble those of acute or chronic tubular nephritis. Thirdly, in some cases the kidneys have shown no sign of disease appreciable by the unaided senses. When these kidneys, either those looking like kidneys with acute and chronic nephritis, or those which look healthy, are examined with the microscope, the changes are not those of inflammation but a degeneration like that which is seen in blood poisoning.

These changes have been variously described by various authors, the following being some of the descriptions. Professor Hamilton says:—

> Judging from the naked-eye appearances we expected that parenchymatous inflammation of the tubular epithelium in the cortex, passing into a state of fatty degeneration, would be revealed. The first glance at a section of the organ, however, showed conclusively that this was not the case and that the lesion was not an ordinary parenchymatous inflammation. It consisted of degeneration of the epithelial cells of a certain proportion of the tubules in the circumferential aspect of the cortex. The degeneration appeared to be of a colloid nature. The products of these degenerated cells ran down and blocked up, more or less completely, the other convoluted and straight tubules, so as to render them functionally useless, although their tissues were not diseased.

Dr. Charlewood Turner, in a case of Dr. Herman's own, says that the sections—

> show recent degenerative changes of the cortex, without any older or cirrhotic lesions, changes attributable to some toxic matter in the blood. Granular degeneration and swelling of the epithelium of the convoluted tubes, the nuclei of which are invisible, and swelling of the connective tissue throughout, without infiltration of leucocytes. In the medullary tissue the epithelium of the loops and connecting tubes appears normal. Some of the loops contain casts. There is much vascular congestion in this part. The glomeruli appear normal. There is no exudation in the capsules.

Dr. W. J. Fenton, reporting upon a case, says:—

> Most tubules show what is apparently a running together of the cells, having no definite structure, and having their nuclei obscured, the whole condition of the epithelium being similar to that often found in acute toxic conditions.

And so on—Dr. Herman's conclusion being that—

> From these different observations, made by independent pathologists, having no hypothesis to support, it follows that, although the kidneys often look like inflamed kidneys, yet that the lesion of puerperal eclampsia is not nephritis but an acute degeneration such as is caused by blood poisons.

It would serve no useful purpose to give all the multitudinous literature of the subject here. The above quotations sufficiently show that the greatest authorities are in complete opposition as to the nature of the renal changes in the kidney diseases to which pregnancy gives rise. One says that they are not nephritic at all; another that they are nephritic, and nephritic in remarkable degree. The matter must remain largely one of opinion.

The crux of the whole question is: What is nephritis? and What are its different kinds? and even to these questions no absolute answer can be given. The varieties of non-suppurative affections of the kidney included under the heading "Bright's disease" run so much into one another and so much confusion has arisen from attempts to keep up a distinction between tubal and interstitial nephritis that it is not to be wondered at that that which some authorities would term a nephritis is refused that title by others.

Dealing with the question from another point view, it will probably be granted that the kidney lesions which occur during and immediately after scarlet fever are those of nephritis. Whether or not the fibrotic changes which may occur in kidneys which have been inflamed during scarlet fever are also inflammatory is doubtful. It is probably incorrect to speak of chronic nephritis in many instances, for

The Effects of the Nephritis upon the Child.

Whether it is that the influence of the nephritis upon the fœtus is bad or that the poor condition of the fœtus is in some way the cause of the nephritis is a moot point. The fact, however, that some of the children are born healthy and live to grow up notwithstanding the renal trouble in the mother would seem to indicate that in the other cases the fœtus suffers because the mother has nephritis rather than *vice versâ*. All statistics show a high mortality amongst the children and those under discussion form no exception. Leaving the eclampsia cases out of account, the other type of patients show that in 18 per cent. of the cases the child was born too premature to live; in 23 per cent. the child was born near to, or at, term, but dead; whilst in the remaining 59 per cent. the child was born alive, but in a number of instances with too little vitality to continue to live long.

Treatment.

It is not the province of these lectures to enter upon treatment at any length, so that but a few words will be said about it. Clearly the treatment of an eclamptic case lies mainly with the obstetrician. That of the nephritis of the earlier months of pregnancy, however, calls for immediate obstetric measures in but a few cases. Rest in bed, with medicinal, dietetic, and other measures precisely similar to those employed in other cases of acute or subacute nephritis, ameliorates the renal symptoms in many of the cases. The œdema and the albuminuria may thereby almost disappear before the end of pregnancy is reached. The average patient of this kind does better when treated upon the same lines as a non-pregnant case than if obstetric measures for the termination of the pregnancy are recommended and adopted. If, however, the renal mischief increases instead of diminishing, as is sometimes the case, notwithstanding all medicinal treatment—particularly when the latter has not been adopted and insisted upon at the very beginning of the trouble—the case will probably require the assistance of an obstetrician before term; although the relief to the nephritis after an artificial termination of the pregnancy is not as a rule so rapid as it is after natural delivery.

PREGNANCY IN PATIENTS WHO HAVE ONLY ONE KIDNEY.

Seeing that so much stress has been laid upon the renal affections that pregnancy itself may cause it might well be asked whether a patient who for one reason or another has had one of her kidneys removed ought to be advised not to marry. It must be remembered that although pregnancy sometimes gives rise to nephritis or to pyelonephritis the total proportion of all cases in which it does so is exceedingly small. Moreover, it is well known that after excision of one kidney the other, if healthy, has a very remarkable power of hypertrophying by way of compensation. Such a single kidney is seen in the post-mortem room now and then and it may weigh nearly as much as two ordinary kidneys. It would be expected, therefore, that if there was no evidence of disease in the remaining kidney and if the patient was otherwise in good health pregnancy might be incurred without any untoward symptoms whatever. This is, in fact, what Mr. G. E. Twynam[7] has found to be the case. It may be added that since the greater strain is put upon the right kidney during pregnancy the case is more likely to do well if it is the left kidney that remains; and further that since compensatory hypertrophy of the kidney must take some time to become complete a year or more should elapse between the nephrectomy and the occurrence of pregnancy in any given case.[8]

TETANY AND PREGNANCY.

Another condition of which pregnancy seems to be one of the causes is tetany. One of the most interesting points in regard to the association of pregnancy with tetany is perhaps its apparent rarity in London. There does not seem to have been a single case of the kind in Guy's Hospital during the last 30 years. The writer has not seen a case of the association, though he has seen several instances of tetany in adults, chiefly in conjunction with gastric lesions. Incidentally, as a point which possibly supports the toxic theory of the disease, it may be mentioned that more than one case excreted quantities of diacetic acid and acetone in the urine. It is well known that both these substances appear in the urines of many cases of gastric disorder quite apart from tetany and that they also appear in conditions of starvation, so that possibly the gastric disorders lead to acetonuria, partly or wholly as the result of semi-starvation. Nevertheless, in an instance recorded by Dr. David Forsyth[9] the paroxysms of tetany in a patient who also had evidence of gastric ulceration were always associated with an increased degree of acetonuria. It would be interesting to know whether diacetic acid and acetone were also present in the urine in cases of tetany associated with pregnancy or in those following operations upon the thyroid gland; and further, whether large doses of sodium bicarbonate had any beneficial effect upon the symptoms and course of the tetany, as might be the case by analogy with the treatment of acidosis in cases of diabetes mellitus.

That pregnancy and tetany are not at all generally related to one another as cause and effect is further shown by the comparatively small amount of literature there is upon the subject. One of the best-known monographs about it is that of Frankl-Hochwart. From this and from other papers one learns three particularly interesting points about the disease—namely, first, that in places where it occurs at all it bears a remarkable relationship to the time of year; the great majority of the cases arise in the late winter and early spring. Out of 59 cases collected by Frankl-Hochwart[10] 39 occurred in January, February, March, or April, whilst only 13 occurred exclusively in the remaining eight months of the year. Secondly, that there is a noteworthy tendency for the disease to be almost epidemic. There is a little difficulty in interpreting some of the accounts, for the disease was undoubtedly diagnosed erroneously in years gone by. Epidemic cerebro-spinal meningitis was formerly confused with tetany, for example. Hysteria affecting many individuals of a township, analogous to that of the dancing Dervishes or to that of the chorea of the ancients, constitutes another difficulty. Even allowing for this, however, the records show clearly that in places where tetany occurs there are some years in which the cases are quite numerous and then others when the disease almost disappears from the neighbourhood. In Paris, for example, where the tetany of pregnancy used to be quite frequent, it is now said to be a condition of great rarity. Thirdly, in correspondence with the above it appears to be a disease of extremely local distribution. Very rare in London, and apparently throughout Great Britain, formerly common in Paris and now rare there, rare throughout America, the two places where it seems to be the reverse of rare are Heidelberg and Vienna. It appears to be endemic in these two cities. It by no means follows, of course, that it is microbial in origin. It is well known that such diseases as cirrhosis of the liver or acute gout, common though they are in some places, are quite rare in others, although there is not yet any proof that either of these is of bacterial origin. There is no reason to suppose that the tetany sometimes associated with pregnancy differs essentially from adult tetany due to other causes. There is no need to discuss its general symptoms here, for they are well known.

The Pathology of Tetany.

The pathology of the condition is obscure, though there is much evidence to show that a toxin, and possibly not always the same toxin, is at work. The morbid lesions that have been described have chiefly been changes in the anterior cornual cells of the spinal cord and the corresponding cells in the medulla oblongata. Such changes would agree with the altered electrical reactions noted in the muscles during life. There is no complete reaction of degeneration, for excitability to the faradic current is retained; but with the galvanic current, instead of the kathodal closure contraction being more easily obtained than the anodal closure contraction, there is an altered polar response which may be summarised by saying that anodal closure contraction and anodal opening contraction are both obtained more readily than kathodal closure contraction. The changes in the spinal cord cells do not seem to be permanent, for the majority of the cases get perfectly well, though there is a tendency for the tetany to recur in several different pregnancies, not necessarily successive, in the same person.

with albumin and renal tube casts in the urine and without eclampsia. The renal symptoms and urinary abnormalities again resolved after the later child was born.

It would be interesting to trace the after-histories of all the cases of eclampsia that have recovered for the time being and note what happened later. The writer has tried to do this with hospital patients, but the number of cases lost sight of is so great that the statistics obtained so far are too small to be of value. This would be a subject very suitable for a collective inquiry. The cases that have been traced show that puerperal eclampsia has recurred in some without necessarily proving fatal; that in others, as has been mentioned, renal œdema without eclampsia has taken its place in a subsequent pregnancy; whilst others, again, having recovered from eclampsia, have borne subsequent children without either œdema, albuminuria, or eclampsia. It is not improbable that the same would be true of scarlatinal nephritis if scarlet fever could recur in the same patient as often as pregnancy can.

Returning now to a consideration of all the cases together, they are found to bear out entirely what has been noted by others in regard to: the relatively better prognosis in the œdema type of pregnancy nephritis as compared with the eclamptic; the high proportion of primiparæ amongst the eclampsia cases and the preponderance of multiparæ amongst those who develop the œdema type of nephritis; the relatively high percentage of cases in which albuminuric retinitis occurs; the relatively greater severity of the symptoms when the uterus contains twins; and the liability for the children to be born prematurely or dead, or for them to die soon after birth.

The immediate maternal mortality.—Out of 71 patients with renal œdema and no eclampsia four died whilst in hospital, an immediate maternal mortality of 5 per cent., whereas out of 51 cases of puerperal eclampsia 15 died, an immediate maternal mortality of 29 per cent. This is a relatively small mortality as compared with that of acute uræmia not associated with pregnancy.

The number of previous pregnancies.—Of the puerperal eclampsia cases 76 per cent. of the patients were primiparæ; of the remainder most had had only one previous child, but in two cases there had been 10 and 12 previous pregnancies respectively. Of the cases with renal œdema and no eclampsia, on the other hand, only 36 per cent. were primiparæ, 64 per cent. having borne a former child or children, whilst a considerable number of the multiparæ had had from four to 12 pregnancies without evidence of nephritis before. Leaving the eclampsia cases aside, as being of less interest to physicians, it is found on analysing the 71 cases in which there was renal œdema without eclampsia that 70 per cent. had never had symptoms of renal disease until the time when they developed during the pregnancy; that 10 per cent. had passed through a former pregnancy without symptoms of nephritis, but subsequently developed them when not pregnant, and suffered from an increase in the symptoms during a later pregnancy; that 7 per cent. had had acute nephritis before they were married and suffered from recrudescence of that trouble during pregnancy; that 6 per cent. had had eclampsia with a former pregnancy and now had symptoms of ordinary nephritis during pregnancy; that 6 per cent. had had symptoms of nephritis during a former pregnancy, recovering between whiles, but exhibiting the nephritic symptoms again when subsequently pregnant (in one of these cases nephritis with œdema, but without eclampsia, had recurred with each of four successive pregnancies); and that 1 per cent. had had no symptoms of nephritis during pregnancy and had had no eclampsia, but developed the symptoms of acute nephritis, with general œdema, during the puerperium.

As regards the month of pregnancy at which the renal trouble became manifest, that of eclampsia was, as all observers agree, in the latest months or immediately following labour; whereas in the cases where renal œdema was the main symptom the onset was at any time between the second and the eighth month, the trouble manifesting itself about the fifth or sixth month in the majority of cases. In this connexion it might be asked: If a pregnant woman develops evident œdema of renal type, with albumin and tube casts in the urine, during the eighth month of pregnancy, what is the likelihood that she will also have eclampsia? It would require a larger number of cases than the above for any absolute answer to be given to this question. It is fairly clear that if nephritis with œdema develops in the early or middle months of pregnancy it is quite exceptional for eclampsia to occur when the pregnancy is more advanced. It is also quite clear that the majority of cases of eclampsia have little or no œdema. Thus in 49 per cent. of the eclampsia cases there was no œdema at all; in 35 per cent. there was definite though slight œdema of the face and ankles; in but eight cases, or 16 per cent., the general œdema was extensive, though it only developed in the later months.

Amongst the renal cases in which no eclampsia occurred there were nine in whom generalised œdema developed for the first time during the eighth month or later. There were thus 17 cases in whom extensive renal œdema first appeared in the eighth month, eight of them subsequently developing eclampsia and nine of them not doing so. It seems therefore that a broad answer to the question propounded above is, that when renal œdema first develops as late as the eighth month of pregnancy, the chances as to whether the patient will suffer from eclampsia or not are about equal.

Albuminuric Retinitis.

It is generally allowed that albuminuric retinitis in these pregnancy kidney cases is more common than it is in other forms of nephritis. The above cases conform with the general conclusions arrived at by others. Unfortunately, there was not an ophthalmoscopic record kept in every instance. Of the 71 cases without eclampsia 13 had albuminuric retinitis, two dying; 10 had no albuminuric retinitis, none dying; and in 48 cases the condition of the eyes is not noted. Even if it be assumed that there was no albuminuric retinitis in all of these, which is improbable, the incidence of the retinal changes is nearly 20 per cent.; whereas in 312 consecutive cases of chronic nephritis not associated with pregnancy the incidence of the retinitis was 11 per cent.—14 per cent. in those diagnosed as chronic tubal and 9 per cent. in those thought to be chronic interstitial nephritis.

It is generally acknowledged that albuminuric retinitis is less likely to occur in acute Bright's disease than it is in chronic; nevertheless, it was well marked in 3 of the eclampsia cases, 2 of them dying. It was absent in 9, of whom none died; and there is no mention of the retinæ in the remainder.

Amaurosis was present in several cases in which the optic discs and retinæ were normal.

It has been said that pregnancy cases with albuminuric retinitis have a less unfavourable prognosis than have others with a similar lesion. This is perhaps true to the extent that in a few instances the retinal mischief has been known to disappear again after the pregnancy is over. In at least one of the above cases in which albuminuric retinitis was well marked during pregnancy the albuminuria, the œdema, and the retinitis disappeared entirely after the child was born. Nevertheless, the presence of the retinal changes is a sign of extreme gravity even in the pregnancy cases, the immediate mortality amongst the 16 cases who had it being 25 per cent.—15 per cent. in the non-eclamptic cases and 66 per cent. in those who had eclampsia.

The Effect of Twins.

The deleterious effect of twin pregnancy upon the kidneys is more marked in the eclampsia cases than it is in those with general œdema without eclampsia. Amongst the 71 cases of the latter there was not one of twin pregnancy, whereas amongst 51 of the former there were twins in 4; that is to say, in 8 per cent. The normal proportion of twin to single pregnancies is as 1 to 80, so that the incidence of twin pregnancies in eclampsia cases is more than six times greater than the average. This is precisely what has also been quoted by Schauta,[3] Hofmeier,[4] Löhlein,[5] Schreiber,[6] and others, whose conjoint statistics show that in between 7 and 8 per cent. of eclampsia cases twins are present. This remarkable fact strongly supports the view that the nephritis is due to a toxin elaborated by the placenta or by the fœtus, for, as Dr. Herman and others point out, the mere bulk of the uterus will not account for it. "Nothing like eclampsia is ever met with in cases of abdominal tumours—ovarian cysts, uterine fibroids, and so forth—which sometimes get much larger than any pregnant uterus. The frequency of eclampsia with twin pregnancy arises from the presence of two children in the womb and not from mechanical distension of the abdomen."

the co-existence of pregnancy makes an attack of appendicitis more severe than the average—cannot be given until, by some process of collective inquiry, all the milder as well as the more severe cases can be collected. This is not at present possible, for the more striking cases become published, the simpler remaining in the background. The proportion of mild to severe cases is thus lost sight of; consequently the severity of appendicitis during pregnancy is very apt to become exaggerated. Nevertheless, those who have seen cases give it as their personal opinion that pregnancy is a complication which greatly increases the risks and dangers of the disease. The attack may occur at any stage of the pregnancy, as early as the sixth week and as late as the eighth month. The illness may be of all degrees of severity, from transient appendicular colic to the acute fulminating appendicitis which proves fatal in a few hours. In mild attacks, during the early months of pregnancy, the inflammation may completely subside and pregnancy go on uninterruptedly to term. "Owing, however, to the increased blood-supply and to the congestion of the parts due to pressure of the enlarging uterus," cases of appendicitis in pregnancy seem to run an unusually rapid course. Though some subside the majority, if left, seem to go on to suppuration and the further advanced the pregnancy the more likely this seems to be.

The danger to the mother's life does not cease with the opening of the abscess, for even after drainage of the cavity in the later stages of pregnancy, or in cases where miscarriage has taken place already, a septic salpingitis or endometritis may be set up with a further liability of extension to the peritoneal cavity. As regards the effects upon the fœtus, the latter was born dead in 90 per cent. of the cases collected by Abrahams.[12] When pus forms in the later months of pregnancy miscarriage almost invariably takes place whether operation be performed or not. Even in cases where no pus is proved to have been present miscarriage or premature labour is more common than is the rule in healthy cases. It is not surprising that an untoward ending of the pregnancy is so frequent when one considers that the enlarged uterus is almost certain to be in contact with the inflamed tissues and to form one wall of the abscess cavity when pus is present.

The answer to the question of whether or not the treatment should be different to that of appendicitis in non-pregnant cases seems to be this: That, upon the whole, operative measures should be accelerated rather than postponed in these pregnancy cases. There are, of course, quite mild cases in which it is better to do nothing active; but in cases of the next degree of severity, where if the patient were not pregnant it might be thought best to wait, the opinion seems to be that operation should be advised on the very ground that the patient is pregnant, particularly in the later months of pregnancy. Doubtless this will not be the opinion of all,[13] but the reasons given for it seem sound; in the first place, owing to the vascularity of the parts, pus is even more likely to occur in these cases than it is in others; in the second place, the prospect as regards the child is so poor in any case that the course followed should be almost exclusively that which is in the greatest interests of the mother; and in the third place, the emptying of the uterus by spontaneous miscarriage or premature labour is so likely to occur and with it a rending open of a previously localised inflammation, with consequent spread to the general peritoneal cavity, that it is very dangerous to wait.

The foregoing argument gives the answer to the last of the questions that were put above. It is in the last degree undesirable that obstetric measures for terminating the pregnancy artificially should be resorted to for fear of breaking down adhesions that are helping to localise the inflammation.

Pinard[14] has collected 45 cases of appendicitis complicating pregnancy, the diagnosis being confirmed in 30 by operation or post-mortem examination. He concludes that appendicitis may attack a pregnant woman at the beginning or at any time during pregnancy; that in the majority of cases it causes abortion, the reason for which is that the fœtus becomes infected with the bacillus coli communis, this organism being recoverable from its blood; that every type of appendicitis may occur, the severer cases predominating; and that operation should be advised as early as possible, both for the mother's sake and with a view to diminishing the chances of fatal infection of the child by the bacillus coli communis.

If a pregnant woman develops an attack of appendicitis that is in any degree severe the statistics that are available all indicate that the best chance of saving both the mother and the child is by early operation.

THE SCHOOL AND ITS PART IN THE PREVENTION OF TUBERCULOSIS.[1]

By JOHN HAY, M.D. VICT., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, LIVERPOOL.

THE subject which I have been asked to discuss with you this afternoon is "The School and its Part in the Prevention of Tuberculosis." The recent legislation dealing with school inspection makes this an opportune moment for carefully reconsidering the many sides to this question and the views which have been expressed by those who have taken an interest in it. I will attempt to place before you some facts bearing on tuberculosis in its relation to the schools and then formulate certain broad lines along which advance seems desirable.

In the last nine or ten years this fight has been actively waged and at last we begin to see undoubted results from our labours. Surely it is a matter of great encouragement that there are those speaking in authority who firmly believe that after another half century of effort tuberculosis will have ceased to be the powerful enemy that it now is. This happy issue, however, can only be attained by unceasing vigilance and continuous effort. One fact alone is sufficient to show what a deadly pest we have in the tubercle bacillus—namely, that one-half of those who die between the ages of 25 and 35 years die from tuberculosis. It is worthy of note that during the last 30 years the death-rate from consumption in England has fallen from 21 to 12 per 10,000 of the population.[2] This grand advance means an enormous saving of human life. But what a different tale your own country tells. 30 years ago your death-rate from consumption was only 18 per 10,000; now it is 22. These figures "give us pause" and are in themselves sufficient to give rise to much searching of heart among those responsible for the guidance of the people in matters of public health. There is no reason why a definite and rapid improvement should not take place in Ireland. What is needed is coördination of the many agencies already in existence, a wider knowledge of the nature of tuberculosis and the means of stamping it out, and last, and of extreme importance, enthusiasm and money. Money is *absolutely essential* in this fight. Every medical man knows well when pondering on the outlook of a patient suffering from pulmonary tuberculosis that the chances of cure, other things being equal, depend on the financial status of the sufferer. The same holds good with a nation. The more money it can afford to put down the better chance there is of a speedy and permanent diminution of the amount of tuberculous disease in the country.

Professor Koch in his Nobel lecture[3] said that he considered "notification, hospitals, sanatoriums, and care-stations the heavy artillery in the battle against tuberculosis," and he says further: "But there are lighter weapons, too, which cannot themselves exercise so incisive an effect but the coöperative help of which we cannot dispense with." Among these he reckons "in the first place, all efforts to instruct the people as to the danger of tuberculosis and to keep awake the interest of the masses in the combating of tuberculosis by popular publications, lectures, exhibitions, and other means."

To-day we are to discuss more particularly the schools and their relation to the prevention of tuberculosis and I venture to think that Professor Koch would have classed the schools as one of the more powerful of the lighter weapons of which

[3] THE LANCET, May 26th, 1906, p. 1449.

The other points that may be of interest are, briefly, the following. The patient usually escapes during the first half of pregnancy, the affection developing in the later months as a rule, though it occasionally shows itself earlier. The spasms are rarely met with during labour—a remarkable point, seeing that they are so readily produced by muscular efforts at other times. They may occur for the first time during lactation, though this seems to be less common than for them to arise during pregnancy and then continue during lactation. If they occur during lactation it is clearly impossible for the mother to suckle the child, for she is unable to hold it securely. It is necessary to feed the baby artificially, not only for its own sake, but also because it leads to the more rapid subsidence of the tetany in the mother. The treatment of the condition is similar to that of tetany in non-pregnant persons. Finally, the tetany in the mother seems to exert less ill-effect upon the fœtus than might be expected.

We may now leave the medical diseases, of which pregnancy is itself the exciting cause, and pass on to the discussion of other medical affections which, though not actually caused by the pregnancy, may yet arise or be already present in a pregnant woman. There is hardly a medical disease, from a common cold to a cancer, that may not be thus present and it is of essential importance to know in what respects, if any, the prognosis and the treatment in the case of a pregnant woman suffering from such intercurrent malady differ from the prognosis and the treatment in other cases. It is manifestly impossible to discuss every such disease in the time at our disposal; many must be left unmentioned.

APPENDICITIS IN ASSOCIATION WITH PREGNANCY.

The question of appendicitis is always one of interest. What is the influence of pregnancy upon appendicitis and *vice versâ?* This would be an excellent subject for a collective inquiry. The number of cases of pregnancy in association with appendicitis seen by a single individual is not likely to be great, and the cases that can be collected from the literature are almost necessarily those which are the more severe. The mild cases, which get better without anything very active being done, escape publication, and a collective inquiry which would cover all cases, whether mild or severe, would probably lead to conclusions that could not but be helpful to all.

There is a certain amount of literature upon the subject, some of which has been collected by Mr. George Heaton[11] of Birmingham General Hospital. One of the chief difficulties in connexion with the matter is that of diagnosis. Inflammatory and other lesions of the right Fallopian tube or ovary may simulate appendicitis very closely. The ordinary vomiting of pregnancy may be regarded as the whole trouble when there is really appendicitis, whilst, on the other hand, when a special outlook is being kept for appendicitis the latter may be diagnosed when none exists. The difficulties that may arise when the lesion is really in the kidney—the pyelonephritis of pregnancy—have already been discussed, and in every case of suspected appendicitis in pregnancy the urine should be carefully examined with the microscope for pus corpuscles. The pains, again, may be referred to the abdomen when the real mischief is in the chest. Indeed, the diagnosis of appendicitis in a pregnant woman is beset with all the difficulties that occur in non-pregnant cases, together with others peculiar to pregnancy. Assuming, however, that the difficulties of diagnosis can be overcome by experience the questions which arise are: Does pregnancy predispose to appendicitis when there has been no previous attack? Does pregnancy in a patient who has formerly had appendicitis without operation render her particularly liable to another attack during or after the pregnancy? Does the coincidence of pregnancy with appendicitis make the latter more severe than it is in average cases? Does appendicitis in the mother render the pregnancy more liable to terminate prematurely and does it militate against the life of the child if the attack occurs when the latter is of viable age? Should the treatment of the appendicitis be precisely similar to that of corresponding attacks in non-pregnant persons, or should the physician's advice be more in the direction of inviting surgical assistance sooner, or more in that of continuing expectant treatment as long as possible in these cases? Should obstetric aid for artificially terminating the pregnancy be sought in any of these cases? These are very vital questions and yet it is by no means easy to answer them. It may be urged that no definite rules can be laid down and that the action to be taken in each instance that arises must be decided entirely upon the merits of the particular case. This is true to a considerable extent; but when it is borne in mind that very different interpretations are put upon these "merits of the case" by different observers, even in cases of appendicitis in non-pregnant persons, it becomes evident that it is still more difficult to decide what is best to be done in cases that are at the same time pregnant.

In answer to the first of the above questions it would seem that pregnancy does not predispose to a primary attack of appendicitis. Amongst all the patients that have been in Guy's Hospital suffering from appendicitis during the last 27 years only one was at the same time pregnant. She was a woman, aged 24 years, who had had no former attack, who had had no previous child, and who was six and a half months pregnant when she was suddenly seized with acute appendicitis of moderate severity. The trouble was localised from the first with the usual fulness in the right iliac fossa. Premature labour came on spontaneously a day or two afterwards and the appendicular trouble rapidly resolved without operation.

The second question receives the following answer from Mr. Heaton: "If a patient have previously suffered from the complaint and afterwards becomes pregnant, the pregnancy may light up another attack. This it probably does by stretching or breaking down old inflammatory adhesions as the uterus enlarges and rises out of the pelvis. ...... On careful questioning it will often be found that there have been one, or several, previous attacks, though in some cases they have been of so mild a character as to have been almost disregarded. ...... Some surgeons would in every case remove the appendix in women immediately after an attack of appendicitis, if they be of a child-bearing age." It is manifestly of the greatest importance to have a clear answer to the question and to know whether the above views are correct or not. A young woman might contemplate marriage and, having had one attack of appendicitis when she was a girl and having recovered from it without operation and having had no symptoms of it since, she might ask the advice of a physician as to whether she ought to have her vermiform appendix removed before her marriage or not. She might be loth to undergo the operation and yet willing to follow the advice that might be given. Ought the operation to be advised in such a case or not? The answer can only be given when the results in a large number of such cases in whom no operation has been done have been collected and analysed. I have attempted to follow a number of hospital cases in this way, but to be of value the statistics obtained in a similar way by many different individuals should be put side by side and compared; the results found so far seem to indicate that there is no particular liability for pregnancy to light up fresh appendicular trouble in cases where the former attack occurred years before and appeared to resolve completely. The fact that a girl with ordinary appendicitis may some day become pregnant and might then have a recurrence of the trouble, may doubtless be an additional argument in favour of appendicectomy during convalescence from the attack, but if a patient has not had that operation at the time and has had no return of the symptoms since, the chances of her developing fresh appendicitis later when she becomes pregnant seem to be sufficiently small to warrant the advice that she needs no operation previously to marriage. If, on the other hand, a woman has her first attack of ordinary appendicitis after marriage, at a time when she is not pregnant, and the question arises as to whether she should have her vermiform appendix removed when the acute phase of the attack has passed, the fact that she might become pregnant very soon would seem to be a very real ground for advising that the operation should be done. Although there seem to be practically no statistics upon the subject, pregnancy arising within a few months of an attack of appendicitis would be very liable, one would think, to stretch and break down the immature adhesions in the way that Mr. Heaton describes, and lead to a recurrence of the trouble at a time when it would be particularly unfortunate. For the same reason it would be unwise for a young woman who had had appendicitis, not years ago but within the last few months, to get married; and such a patient would probably be advised to have appendicectomy performed, even though for a similar state of affairs in a man the operation might not be essential.

The answer to the third question—namely, whether or not done in the improvement of the hygiene of many school premises throughout Great Britain and perhaps in some respects more especially in Ireland. The Commissioners of National Education in Ireland for 1905–06 revealed a condition of affairs which was simply appalling.[5] The whole system of primary education, so far as it concerned the provision of proper school accommodation, was in a state of paralysis. The details concerning some of the Belfast schools are almost incredible.[6] In one school, for example, in Belfast 401 children were present, though there was only accommodation for 209. In another 78 infants were huddled in a room 19 feet by 9½ feet, and 64 first standard pupils in a room 14 feet by 9½ feet, with only one window admitting of being opened. It is hard to believe, for instance, that there are very many schools throughout Ireland that are never washed from one year's end to the other; they are only brushed. I have it on the authority of Mr. Patrick Gamble, the President of the Irish Teachers' Association, that it is no unusual thing for the teacher to have to pay out of his own small stipend for the whitewashing and other necessary repairs about the school. I will not multiply instances; the above will suffice to show at least one flaw to be remedied. It has been well said, "damp, ill-lighted, and dirty schools were forcing-beds for consumption and other diseases." To remedy this, overcrowding must be prevented and a larger air space per child must be enforced. The classes which at present are almost invariably too large must be diminished. The ventilation which in most cases is imperfect should be made efficient. To effect these reforms it will be necessary in many instances to pull down and utterly destroy the old and insanitary and impossible schools and to build new ones in their stead. To tinker up the old schools is a waste of time and is bad economy. However, more can be done for the children with latent tuberculosis than simply giving them fresh healthy surroundings during school hours, though that in itself is half the battle. I will refer to this shortly.

---

[11] Brit. Med. Jour., March 4th, 1905, pp. 463-465.

It is obvious, then, that the children in attendance at school can be divided into three classes: (1) those who are healthy and free from any taint of infection—this division will include the majority of the children; (2) those who are suffering from active consumption, about ½ per cent.; and (3) those who are predisposed to consumption and who are possibly the victims of latent and unrevealed tuberculosis. In this group we may include those children who come from a home where one of their parents or relatives is suffering from "open" tuberculosis.

In order to have the children so classified two things are necessary. First, the medical inspection of school children. This we in England have now obtained under the Education Act of 1907. Secondly, the notification of tuberculosis—the more complete and compulsory the better; this we have in some degree. The Act which has given us medical inspection of schools has left the local education authorities to decide to what extent their medical officer shall work in conjunction with the public health department, and very considerable differences of opinion exist as to the extent to which the school medical officer shall be under the jurisdiction of the medical officer of health. In the memorandum issued by the Board of Education on the medical inspection of children in public elementary schools the Board takes the view "that the work of medical inspection should be carried out in intimate conjunction with the public health authorities and under the direct supervision of the medical officer of health." For, as they point out, "*school hygiene* cannot be divorced from *home hygiene*, and this in turn is intimately bound up with the hygienic conditions of the community." Efficiency and economy require, therefore, an organic relationship between the daily work of the school authority and of the authority responsible for the administration of the wider branches of public health.

The value of a close relationship between the medical officer of the school and the medical officer of health is at once apparent in connexion with this question of open tuberculosis in the homes of the children, for it is essential that the school medical officer should be informed of all cases of tuberculosis present in the homes whence the children come. These children could then be specially supervised and if need be given special care. The medical officer of health on his part, by means of inspectors, &c., would do what lay in his power to educate the consumptive parent as to the necessary hygienic measures and when advisable suggest the removal of the infectious person to the union infirmary. It is generally accepted that latent tuberculosis is more frequently found among the children of consumptives and also that the children of tuberculous parents are predisposed to infection. Thus it is very desirable that the existence of "open" tuberculosis in the parent or parents of the children should be reported to the medical man in charge of a school. With the facts obtained by a careful medical examination and the data supplied by the public health department the children may be classified as I have suggested and can then be dealt with according to their class. Those who have active tuberculous disease must not be allowed to continue in attendance; the medical officer of health should be notified and the parents told to obtain medical advice either from their own medical man or if too poor, to attend a hospital. In a few instances sanatorium treatment might be advisable. The question how to deal with the much larger group of children—those who are predisposed to phthisis or who have tuberculous parents at home—is much more difficult and much more important. Various methods have been employed. In France, in Germany, and in a few instances in England there are schools in the country where the children can receive the benefit of appropriate treatment and proper nourishment while at the same time they are being educated. In England these schools are private ventures but in France and Germany I understand there are special primary schools; more than that, there are sanatoriums and nursing homes and open-air schools. At the best, however, the method is expensive and can only be largely utilised when taken up by the Government or by some wealthy philanthropic body. In the industrial day-schools, where the children are fed as well as taught, it is not difficult to increase the dietary of those who are predisposed to tuberculosis and to order them cod-liver oil and so forth but in the primary and secondary schools it is more difficult. Something should be done by notifying the parents of the importance of a full diet and it might be possible to take special measures during school hours. These are the children to be more particularly considered and whose resisting power must be increased by every available means. They *must not be overworked*, they must have *sufficient sleep*, and they *must be well fed*. A *careful record of their weight* would be of value as an indication of the effect of the stress of school life and of the special treatment which they receive.

The most important hygienic step is, however, the segregation of those incurable cases of pulmonary tuberculosis which are a constant menace to the health of all who come into close contact with them. The house becomes infected, and the infants and young children toddling about and crawling over the infected carpets and floors take in those bacilli which in later years will cause their death.

Dr. A. Newsholme believes that the more rapid reduction of the death-rate from consumption in England as compared with Ireland and France is due to the segregation of so many advanced cases in the workhouse infirmaries.[7] For three years I was assistant medical officer in a large union infirmary where the tuberculous patients formed a fair percentage of the inmates. There were about 80 cases of advanced phthisis in a hospital of some 700 beds. Other union infirmaries tell the same tale. In this way many dangerous sources of infection are removed. Ireland appears to be realising the importance of this, for I see that during 1907 973 deaths from tuberculosis were registered in the city of Dublin; and of these 321 died in workhouses, 271 died in hospital, and only 381 of the 973 died in private houses. The more this method of segregation can be carried out the better for the community and I look forward to the time when the municipalities, in addition to providing wards or "homes" for incurable and disabled consumptives, will have open-air industrial colonies for those who, while suffering from tuberculosis, are still able in some degree to support themselves. These colonies would be of great service in yet more fully localising and isolating cases of open tuberculosis. Segregation is the thing to be aimed at, for to prevent infection is to prevent tuberculosis. By segregation of the infectious cases we purify the homes, and nothing makes for healthy children more than healthy homes. The home is the point at which health must ultimately be controlled.

The inspection of the school medical officer must, of use can be made. There are certain facts which must be fully realised at this point and which I venture to state somewhat dogmatically. 1. Tuberculosis of infants and young children is almost always due to human infection; any other source of infection is almost negligible. The disease in nearly every instance is contracted at home. Home infection is far more common than any other. 2. Pulmonary tuberculosis or consumption is classed as either "open" or "closed." Patients suffering from "open" tuberculosis discharge tubercle bacilli into the surrounding air by means of expectoration or in the spray inevitably associated with a cough. A patient with "open" tuberculosis is an infecting and infectious agent. When, however, there is no discharge of bacilli, as when the disease is early or quiescent and the expectoration when present is free from tubercle bacilli, the patient is then classed as a case of "closed" tuberculosis and is not a source of danger to others. 3. Latent tuberculosis is practically always closed and non-infectious. It is common in school children. Naegeli[4] at Zürich has shown that of the children between the ages of 5 and 14 years who died and on whom a post-mortem examination was made 33 per cent. had some focus or other of tuberculous disease; similarly between the ages of one and five years 17 out of every 100 children going to necropsy were found to be infected. These facts in themselves speak strongly in favour of the home as the source of infection. We may take it, therefore, as correct that in the majority of instances tuberculosis is contracted in infancy or childhood, remains latent and unrevealed during school life, and only becomes evident in adolescence or early manhood.

---

[5] THE LANCET, Oct. 6th, 1906, p. 951.

[6] THE LANCET, July 14th, 1906, p. 123.

[7] THE LANCET, June 2nd, 1906, p. 1544.

I propose to deal with our subject under three heads. 1. To consider how many school children are actually infected and the nature of the infection. 2. To discuss what steps should be taken to lessen the risk of infection and to cure those already diseased. 3. To determine what can be done to make the school a more potent factor for good, for the school is the place where the public opinion of the future is largely formed and where new views of hygiene are to be inculcated.

Is revealed tuberculosis common among the school-going population? The answer to this is in the negative. This matter has been investigated by several men during the last few years and in THE LANCET of Dec. 28th, 1907 (p. 1813), a series of interesting figures is given by Dr. H. C. Lecky and Dr. W. Claude Horton bearing on this point. My own experience tallies with theirs. During the last three years I have investigated 436 children in a Liverpool day industrial school. Every child is examined on admission and once a year afterwards. He or she is stripped to the waist and carefully overhauled. Of the 436 children 397 presented no evidence of lung disease or any form of discoverable tuberculosis. Of the 39 abnormal children two were suffering from definite pulmonary tuberculosis, one had an ankylosed hip-joint the result of old tuberculous trouble, and three had definite tuberculous glands in the neck. The other 33 were affected with slight simple bronchitis. 1 child in 218 was suffering from demonstrable consumption; in other words, only 0·45 per cent.—that is, less than ½ per cent. of the children attending this school—showed any sign of tuberculous disease of the lungs. These results may be tabulated as follows:—

Total.	No lung trouble or tuberculous disease.	Pulmonary tuberculosis.	Other tuberculous affections.	Slight bronchitis.
436	397	2	4	33
—	—	0·45 per cent.	0·91 per cent.	7·5 per cent.

These figures are in keeping with the results obtained by Dr. Lecky and Dr. Horton, who found three cases of revealed pulmonary tuberculosis in 806 children. In London out of 1670 children only 8, or 0·47 per cent., showed signs of consumption. In Blackburn, Dr. A. Greenwood states, among 400 children only one was diagnosed as suffering from pulmonary tubercle. Dr. A. P. Low in Dundee found no consumption in 517 children. Dr. R. V. C. Ash in Dunfermline examined 1371 children with a similar negative result. Dr. W. M. Mackenzie met with 14 cases in the examination of 600 children, while in Aberdeen Professor M. Hay in another series of 600 children found only three infected. In the Cannongate Schools in Edinburgh 19 children were found to be consumptive out of 1318. These results are somewhat contradictory, and I believe that probably the lower estimates are the more correct. However, even including the Edinburgh figures the resulting average is not more than one case of pulmonary tuberculosis in 154 children. Professor E. J. McWeeney of Dublin in a recent paper proves that the percentage of children in the Irish schools suffering from tuberculosis is higher than in the English, and estimates that about 3700 children are actually attending school suffering from "open tuberculosis." He states also that for every six children between 10 and 15 years of age who die from tuberculosis in England 15 die in Ireland; and for every adolescent between 15 and 20 years of age who dies in England three die in Ireland. These numbers are, of course, relative to the total population. In spite of these figures, however, we see that the percentage of children attending school who are suffering from pulmonary tuberculosis is extremely small.

Some very interesting figures were published by Dr. A. Greenwood showing the results of the examination of 1028 children who had absented themselves from school because of illness; of these absentees 6·7 per cent. were suffering from pulmonary tuberculosis. When this high percentage is compared with the relatively low figures just quoted of the extent of pulmonary tuberculosis among the ordinary school children the obvious inference is that tuberculosis when attacking children rapidly unfits them for school life. For this very reason they soon cease to be a source of danger in the school, for they do not attend. Children with acute or subacute tuberculosis are hardly ever found at school, they are rapidly incapacitated and remain at home.

The view of Calmette, von Behring, and others that infection occurs during the earlier years is becoming generally accepted; the results of Naegeli at Zürich, to which I have already referred, bear this out. You will remember that he found among the children from 5 to 14 years of age dying from all causes 33 per cent. who showed some focus of tuberculous disease and similarly that in the children who died between the ages of one year and five years 17 per cent. were more or less tuberculous. Of these tuberculous infants and children, in the large majority of instances the disease would be latent, or, at any rate, unrevealed during life. The late Professor Granchet carried out some interesting investigations bearing upon this point. During three years 4227 children in the primary schools in and near Paris were examined in order to find out how many showed a characteristic *predisposition* to tuberculosis. The result of this investigation was as follows. From 11 to 14 per cent. of the boys and from 17 to 20 per cent. of the girls, or roughly 15 per cent. of the children examined, showed a definite predisposition to tuberculous disease. The existence of this large number of school children predisposed to tuberculosis is a fact of the greatest moment. This predisposition is shown in many ways, as, for example, by the presence of enlarged tonsils and adenoids, with the consequent mouth-breathing, and by poorly developed chests and deficient expansion. Enlarged glands in the neck and abdomen in the majority of instances can be put down to tuberculous infection. Calmette's ophthalmic reaction may possibly prove of service in helping to pick out those children who have some concealed focus of tuberculous disease. The future of these children depends on their resisting power and their resisting power is largely dependent on their environment not only in the home but also in school. The latent tuberculosis present in the 10 or 15 per cent. of the children will not in many instances continue to be dormant. If the resisting power of the children is allowed to remain at a low level sooner or later the tubercle bacilli which have remained concealed in their tissues will again become active and the patient will die during adolescence or early manhood. These facts insisting on the large extent of latent infection have a very practical bearing. They demonstrate the vital importance of healthy surroundings during school hours. It is very difficult in many instances to alter materially the home surroundings of the children but this is not the case with the schools. To have overcrowded, badly ventilated, stuffy schoolrooms is to devitalise the children and to invite disaster. Those predisposed to tuberculosis will have their chances of reaching manhood and womanhood seriously diminished.

I think I am right when I say that much remains to be within 24 hours. Doses of from 1 to 5 cubic centimetres are more or less uncertain in their action, but a dose of 10 cubic centimetres is fatal for a guinea-pig weighing from 200 to 300 grammes within 24 hours.

---

[4] Quoted by Dr. N. Méry, Rapports présentés au Congrès International de la Tuberculose, Paris, 1905, p. 298.

The post-mortem lesions are limited to the stomach and always occur during the first 24 hours after injection. If an animal survive, lesions are found on the next day in its stomach if the dose has been sufficient, and no further lesions nor any symptoms occur after this time. The intestine may be extremely congested but shows no other lesion. This limitation of the lesions to the stomach does not indicate that the serum is specific in its action. Other tissues are also affected as the symptoms and death of the animal shows. I have proved that this is the case by studying the action of the serum on other tissues *in vitro*, and also by showing that sera formed against other tissues are able to produce, although to a less extent, precisely similar lesions in the stomach. The lesions consist of patches of necrosis in the mucous membrane. The areas of necrosis are stained black by altered blood pigment; they are usually multiple and very often nearly the whole mucous membrane is affected, but sometimes only two or three patches may be present or even one only. The patches vary in size from that of a pin's head to that of a large area occupying a third or more of the mucous membrane of the stomach. The patches are sharply marked off from the rest of the mucous membrane which appears to be normal and they are found most commonly near or on one of the curvatures, but may occur anywhere in the stomach. After from 24 to 48 hours the black tissue has completely disappeared, leaving perfectly clean and sharply punched-out ulcers.

On microscopic examination the necrosed patches are quite sharply marked off from the normal tissue and do not extend beyond the *muscularis mucosæ*, the muscular and peritoneal coats being normal.

The blood in the vessels is generally normal and frequently so when they are situated in the necrosed patch. In other cases it is hæmolysed and may occasionally infiltrate the submucous tissue. The gland cells in the necrosed patch are either very faintly stained, or quite unstained, their outlines being clouded and the cells shrunken, or the whole patch may look like a brownish coagulated mass in which no structure can be made out; at other times strands of interstitial tissue alone are seen, the gland cells having completely disappeared. The process evidently begins at the free surface of the mucous membrane and extends towards the bases of the glands, because cases are seen in which some patches are situated on the surface of the mucous membrane only. After 48 hours the edges and base of the ulcer are found to be infiltrated with leucocytes.

In order to study the healing of these ulcers I have found it necessary to inject the serum directly into the stomach wall of the guinea-pig after opening the abdomen aseptically, because if one injects into the blood stream an amount sufficient to produce ulceration the animal nearly always dies. If 2 cubic centimetres of normal guinea-pig's serum, normal rabbit's serum, or salt solution be injected into the wall of the guinea-pig's stomach so as to cause a local œdema, it will be found by the next day or the day after that the solution has been completely absorbed and that no lesion has resulted; but if 1 cubic centimetre or 1½ cubic centimetres of the gastrotoxic serum be similarly injected an ulcer will result. In this way an ulcer similar to those described above may be produced without toxic symptoms. The size of the ulcer depends on the strength and amount of the serum injected. The mucous membrane overlying the injected spot necroses and by the fourth or fifth day has separated, leaving a cleanly punched-out ulcer. I have followed the stages of healing of such ulcers and have found that they become completely healed in from 14 to 28 days, leaving only more or less thickening of the peritoneum and sometimes a little puckering of the mucous membrane. So that one has here a poison which on injection into an animal causes a day's general illness, and if the animal survive leaves ulceration of the stomach which heals up as ulcers produced experimentally in other ways do in from 14 to 28 days. The ulcer may not heal in this way but on the third or fourth day may perforate and give rise to death from general peritonitis, or it may form a local abscess by adhesion to a neighbouring organ. No perforation or local abscess is formed after the first few days. No doubt if it encountered a large blood-vessel gastric hæmorrhage would result.

Mode of action of the gastrotoxin.—I have been able to show that the gastrotoxin of itself is unable to produce necrosis and ulceration of the mucous membrane of the stomach. The actual necrosis is brought about by the gastric juice, and if the gastric juice be put out of action no microscopic lesion can be found as the result of the action of the serum. Although some authorities at the present day consider that the gastric juice plays an important part in the production of gastric ulcer, whilst others deny this supposition, I have not been able to find any experimental evidence that self-digestion actually occurs. Of course, it is quite clear that if the gastric cells are killed by any means, as, for instance, when the blood-supply is cut off or by mechanical or other injury, the gastric juice will digest them, as it does any foreign proteid substance, but I refer to self digestion of the stomach in which the gastric juice attacks a gastric cell which shows no deviation from the normal on microscopic examination.

In order to put the gastric juice out of action, whilst the poison is acting, it is merely necessary to introduce into the guinea-pig's stomach by an œsophageal tube about 15 cubic centimetres of sodium bicarbonate solution, of any strength from 0·8 per cent. upwards, before injecting the serum into the peritoneal cavity. At the same time a control guinea-pig must be injected with the same amount of the same serum at the same time. I have done many such experiments and in all the cases in which the gastric juice was previously neutralised no necrosis of the stomach was produced, but in all the control animals the usual black patches were visible in the mucous membrane. The poison therefore produces some change in the gastric cells which renders them susceptible to the action of the gastric juice. This result is important from the point of view of cytotoxins, because so few observers have ever been able to find any microscopic change on injecting different cytotoxins, and my results show that a change really does occur although it cannot be detected histologically. It is also important from the point of view of gastric ulceration, because it proves that a poison may circulate in the blood which is capable of initiating self-digestion. Whether this is brought about by the neutralisation of some specific resisting power possessed by the cells or whether by merely injuring them, in which case many other poisons may be capable of bringing about the same result, is a very important question. Further observations which I have made tend to show that it is a question of injury to the cell, because other poisons, which cannot be supposed to have any influence on any supposed specific resisting power, may, like gastrotoxin, initiate self-digestion.

Cytotoxic sera obtained by injection of liver cells, cells of the mucous membrane of the intestine, and red blood corpuscles produce necrotic patches in the stomach, which I have shown to be the result of self-digestion by the method of neutralisation of the gastric juice. These sera do not produce such a marked effect upon the stomach as gastrotoxic serum, but when they do produce lesions they are of the same nature. It is therefore probably a fact that all the cytotoxic sera contain a common protoplasmic poison, which is especially toxic for the kind of cell against which it has been formed, but which acts upon all other kinds of cells to a less extent; or if each poison formed against a separate organ is distinct, then they are so nearly allied that their actions overlap and destroy their specificity.

Certain protoplasmic poisons introduced into the stomach may likewise initiate self-digestion by injuring the cells. In the case of the guinea-pig dilute hydrochloric acid up to the strength of 0·7 per cent. may be introduced into the stomach and no harm will result, but if the strength exceed this necrosis of the stomach and ulceration will be produced. Dilute sulphuric acid above 0·8 per cent., dilute lactic acid above 4 per cent., and dilute acetic acid above 2 per cent. will also produce necrosis. If the animal be poisoned with gastrotoxic serum the introduction of these solutions into the stomach, in much greater dilution than is necessary to produce necrosis, will markedly increase the lesions. For instance, if a guinea-pig be injected with a dose of the serum and if at the same time a 0·3 to 0·7 per cent. solution of hydrochloric acid, which is itself inactive, be introduced into the stomach the lesions are much more marked than in the control animal. One has here the two protoplasmic poisons combining to produce self-digestion. It is not possible for hyperacidity of the gastric juice ever to reach such a height as to cause ulceration of itself, but it may increase the tendency to such ulceration not by increasing the peptic activity of the gastric juice but by acting as a protoplasmic poison.

course, include the teachers, the caretaker, and any other persons employed on the school premises. It is well known what a high mortality from consumption there is amongst teachers. I have a very vivid recollection of my Latin master who coughed and hawked away for several years until in the end he became incapacitated by the pulmonary tuberculosis from which he ultimately died. With adequate medical inspection such a thing to-day would not be possible. This high mortality among teachers is a grave reflection on the ventilation and general hygiene of the schools where they have to work.

We now come to the third division of our subject—namely, the importance of the school as a factor in the formation of public opinion, in the dissemination of correct ideas concerning tuberculosis, and in the education of the parents by the children. This factor I believe is of far-reaching and cumulative importance. In spite of all that has been written and said during the last ten years the great bulk of the poorer classes have as yet only the vaguest and often incorrect ideas concerning consumption and the means by which the infection is spread. As an example of this let me tell you the following. A man who was suffering from somewhat extensive pulmonary tuberculosis was being carefully instructed by his medical attendant about the importance of always destroying his sputum either by spitting into a cup containing a disinfectant or by burning it in the fire. He answered, "Oh, doctor, you needn't trouble about me, for whenever I spit I put my foot on it!" When the children once get accurate knowledge of these matters such ignorance will rapidly disappear. There is no more talkative missionary than a youngster full of what he considers important information. The children must be taught the elementary facts concerning the hygiene of tuberculosis, the close relationship between alcoholism and consumption, the dangers of expectoration and coughing, the infectivity of consumption, the value of fresh air, and the many measures to be adopted to prevent the spread of the disease. In order to have this effectually done I would include hygiene and temperance among the subjects concerning which the inspectors must report.[8] The teachers themselves must first be taught and I strongly urge that they should be very thoroughly grounded in the fundamental facts bearing on infection, the varying virulence of the infective agent, and the differing resisting power of the host or person infected. To quote Professor H. Corby, "The teacher should strive to become an apostle and evangelist of hygiene."[9]

Enthusiasm in the teachers begets enthusiasm in the taught. Children have a lively sense of their importance and many of them are delighted to be charged with a gospel. As an example of the help which they can at times give Dr. E. W. Hope, the medical officer of health of Liverpool, tells me that at the time of the last census all the teachers of the elementary schools in Liverpool explained the meaning of the census to the children with the help of a leaflet issued by the public health department. The youngsters went home full of importance and helped their parents to fill in the necessary form with the result that the returns were much more accurate than usual.

To summarise, in conclusion:—1. Without infection there is no tuberculosis. 2. Pulmonary tuberculosis is either "open," in which case the patients are infectious, or "closed," then the patients are not dangerous to others. 3. School-going children as a class are healthy, only ½ per cent. show definite signs of pulmonary tuberculosis. About from 10 to 15 per cent. are predisposed to consumption and in all probability suffer from latent tuberculosis. Special care should be given to these children. 4. In Ireland these percentages are higher. The *periodical medical examination* of the scholars, teachers, and caretakers is essential, and every effort should be made to obtain this boon for Ireland. 5. School hygiene cannot be divorced from home hygiene. 6. The active coöperation of the school medical officer and the medical officer of health is most desirable and tends to efficiency and economy of administration. 7. Tuberculosis of infants and children is almost always due to human infection and that infection generally occurs at home. 8. The segregation of incurable and dangerous consumptives in union infirmaries and elsewhere will greatly diminish the incidence of infection among infants and young children. 9. The children must be utilised to educate their parents. The schools should be centres for the dissemination of accurate information concerning consumption and thus help to form public opinion.

THE EXPERIMENTAL PRODUCTION OF GASTRIC ULCERATION BY INJECTION OF GASTROTOXIN.[1]

BY CHARLES BOLTON, M.D., D.SC. LOND.,
M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL;
RESEARCH SCHOLAR OF THE GROCERS' COMPANY.

FOR the past five years I have been working upon the pathology of gastric ulceration from an entirely new point of view. Some of my results have already been published in three communications to the Royal Society,[2] and it is my intention to-night to give you a short *résumé* of the main features of the work.

Starting from the facts that specific bacteriolytic sera could be obtained which would destroy the bacteria against which they were formed, and that similarly hæmolytic sera active against red blood corpuscles and in a few instances cytolytic sera had been produced, I conceived the idea of preparing a gastrotoxic serum active against gastric cells, thinking that this would throw light not only upon the phenomena of cytotoxic action but also upon the obscure problem of gastric ulceration. I succeeded in producing such a serum, and without further introduction will describe—first, the method of preparation of the serum; and secondly, the action of the serum: (*a*) on injection into the living animal and (*b*) in the test tube.

I.—*Method of Preparation of the Serum.*

The serum is prepared by injecting the gastric cells of one animal into another, the blood serum of the injected animal becoming poisonous for the kind of gastric cells which have been injected. Three sera have in this way been obtained: (1) By injection of the gastric cells of the guinea-pig into the rabbit; (2) by injection of the gastric cells of the rabbit into the rabbit; and (3) by injection of human gastric cells into the rabbit or the domestic fowl. The human stomach was obtained from operation cases at the hospital, the mucous membrane being scraped off and injected forthwith into the rabbit or fowl. In the other cases the rabbit or guinea-pig, as the case may be, whose gastric cells are to be injected is starved for 24 hours to insure the stomach being empty. The animal is killed, the thoracic viscera are cut out, and a cannula is inserted into the thoracic aorta, through which a stream of sterilised salt solution is run until the abdominal organs are washed quite free from blood. The stomach is cut out, opened, and thoroughly washed. The mucous membrane is then scraped off on a sterilised plate, ground up into an emulsion with salt solution, and injected into the peritoneal cavity of a rabbit. A fresh filtered extract of mucous membrane may be used, but it takes longer to prepare and on the whole does not possess any advantages over the injection of the cells themselves. After seven or ten days the injection is repeated, and when four or five have been given the blood serum of the injected rabbit is found to be highly toxic. The blood is obtained by opening a vessel of the ear, and in this way from 30 to 40 cubic centimetres can easily be obtained each week. The animal may be thus alternately bled and injected for about two months, or more in some cases, after which the toxicity of the serum falls. The blood is whipped and centrifugalised and the serum is always used fresh on the day on which it is obtained. I have immunised more than 150 rabbits in this way during the course of my work.

II.—*Action of the Serum on Injection.*

The following remarks apply to the serum obtained by injecting the rabbit with guinea-pig's stomach cells. No lesion is found in the stomach of the rabbit which has formed the gastrotoxin and no lesion results on injection of the serum into another rabbit. In half an hour after intraperitoneal injection of the serum into a guinea-pig the symptoms of intoxication are well marked and death occurs within 24 hours. Doses of from 1 to 5 cubic centimetres are more or less uncertain in their action, but a dose of 10 cubic centimetres is fatal for a guinea-pig weighing from 200 to 300 grammes within 24 hours.

---

[1] A paper read before the Medical Society of London on Feb. 24th, 1908.

[2] Proceedings of the Royal Society: (*a*) vol. lxxiv., p. 135, 1904; (*b*) B. vol. lxxvii., p. 426, 1906; (*c*) B. vol. lxxix., p. 533, 1907.

The post-mortem lesions are limited to the stomach and always occur during the first 24 hours after injection. If an animal survive, lesions are found on the next day in its stomach if the dose has been sufficient, and no further lesions nor any symptoms occur after this time. The intestine may be extremely congested but shows no other lesion. This limitation of the lesions to the stomach does not indicate that the serum is specific in its action. Other tissues are also affected as the symptoms and death of the animal shows. I have proved that this is the case by studying the action of the serum on other tissues *in vitro*, and also by showing that sera formed against other tissues are able to produce, although to a less extent, precisely similar lesions in the stomach. The lesions consist of patches of necrosis in the mucous membrane. The areas of necrosis are stained black by altered blood pigment; they are usually multiple and very often nearly the whole mucous membrane is affected, but sometimes only two or three patches may be present or even one only. The patches vary in size from that of a pin's head to that of a large area occupying a third or more of the mucous membrane of the stomach. The patches are sharply marked off from the rest of the mucous membrane which appears to be normal and they are found most commonly near or on one of the curvatures, but may occur anywhere in the stomach. After from 24 to 48 hours the black tissue has completely disappeared, leaving perfectly clean and sharply punched-out ulcers.

On microscopic examination the necrosed patches are quite sharply marked off from the normal tissue and do not extend beyond the muscularis mucosæ, the muscular and peritoneal coats being normal.

The blood in the vessels is generally normal and frequently so when they are situated in the necrosed patch. In other cases it is hæmolysed and may occasionally infiltrate the submucous tissue. The gland cells in the necrosed patch are either very faintly stained, or quite unstained, their outlines being clouded and the cells shrunken, or the whole patch may look like a brownish coagulated mass in which no structure can be made out; at other times strands of interstitial tissue alone are seen, the gland cells having completely disappeared. The process evidently begins at the free surface of the mucous membrane and extends towards the bases of the glands, because cases are seen in which some patches are situated on the surface of the mucous membrane only. After 48 hours the edges and base of the ulcer are found to be infiltrated with leucocytes.

In order to study the healing of these ulcers I have found it necessary to inject the serum directly into the stomach wall of the guinea-pig after opening the abdomen aseptically, because if one injects into the blood stream an amount sufficient to produce ulceration the animal nearly always dies. If 2 cubic centimetres of normal guinea-pig's serum, normal rabbit's serum, or salt solution be injected into the wall of the guinea-pig's stomach so as to cause a local œdema, it will be found by the next day or the day after that the solution has been completely absorbed and that no lesion has resulted; but if 1 cubic centimetre or 1½ cubic centimetres of the gastrotoxic serum be similarly injected an ulcer will result. In this way an ulcer similar to those described above may be produced without toxic symptoms. The size of the ulcer depends on the strength and amount of the serum injected. The mucous membrane overlying the injected spot necroses and by the fourth or fifth day has separated, leaving a cleanly punched-out ulcer. I have followed the stages of healing of such ulcers and have found that they become completely healed in from 14 to 28 days, leaving only more or less thickening of the peritoneum and sometimes a little puckering of the mucous membrane. So that one has here a poison which on injection into an animal causes a day's general illness, and if the animal survive leaves ulceration of the stomach which heals up as ulcers produced experimentally in other ways do in from 14 to 28 days. The ulcer may not heal in this way but on the third or fourth day may perforate and give rise to death from general peritonitis, or it may form a local abscess by adhesion to a neighbouring organ. No perforation or local abscess is formed after the first few days. No doubt if it encountered a large blood-vessel gastric hæmorrhage would result.

Mode of action of the gastrotoxin.—I have been able to show that the gastrotoxin of itself is unable to produce necrosis and ulceration of the mucous membrane of the stomach. The actual necrosis is brought about by the gastric juice, and if the gastric juice be put out of action no microscopic lesion can be found as the result of the action of the serum. Although some authorities at the present day consider that the gastric juice plays an important part in the production of gastric ulcer, whilst others deny this supposition, I have not been able to find any experimental evidence that self-digestion actually occurs. Of course, it is quite clear that if the gastric cells are killed by any means, as, for instance, when the blood-supply is cut off or by mechanical or other injury, the gastric juice will digest them, as it does any foreign proteid substance, but I refer to self digestion of the stomach in which the gastric juice attacks a gastric cell which shows no deviation from the normal on microscopic examination.

In order to put the gastric juice out of action, whilst the poison is acting, it is merely necessary to introduce into the guinea-pig's stomach by an œsophageal tube about 15 cubic centimetres of sodium bicarbonate solution, of any strength from 0·8 per cent. upwards, before injecting the serum into the peritoneal cavity. At the same time a control guinea-pig must be injected with the same amount of the same serum at the same time. I have done many such experiments and in all the cases in which the gastric juice was previously neutralised no necrosis of the stomach was produced, but in all the control animals the usual black patches were visible in the mucous membrane. The poison therefore produces some change in the gastric cells which renders them susceptible to the action of the gastric juice. This result is important from the point of view of cytotoxins, because so few observers have ever been able to find any microscopic change on injecting different cytotoxins, and my results show that a change really does occur although it cannot be detected histologically. It is also important from the point of view of gastric ulceration, because it proves that a poison may circulate in the blood which is capable of initiating self-digestion. Whether this is brought about by the neutralisation of some specific resisting power possessed by the cells or whether by merely injuring them, in which case many other poisons may be capable of bringing about the same result, is a very important question. Further observations which I have made tend to show that it is a question of injury to the cell, because other poisons, which cannot be supposed to have any influence on any supposed specific resisting power, may, like gastrotoxin, initiate self-digestion.

Cytotoxic sera obtained by injection of liver cells, cells of the mucous membrane of the intestine, and red blood corpuscles produce necrotic patches in the stomach, which I have shown to be the result of self-digestion by the method of neutralisation of the gastric juice. These sera do not produce such a marked effect upon the stomach as gastrotoxic serum, but when they do produce lesions they are of the same nature. It is therefore probably a fact that all the cytotoxic sera contain a common protoplasmic poison, which is especially toxic for the kind of cell against which it has been formed, but which acts upon all other kinds of cells to a less extent; or if each poison formed against a separate organ is distinct, then they are so nearly allied that their actions overlap and destroy their specificity.

Certain protoplasmic poisons introduced into the stomach may likewise initiate self-digestion by injuring the cells. In the case of the guinea-pig dilute hydrochloric acid up to the strength of 0·7 per cent. may be introduced into the stomach and no harm will result, but if the strength exceed this necrosis of the stomach and ulceration will be produced. Dilute sulphuric acid above 0·8 per cent., dilute lactic acid above 4 per cent., and dilute acetic acid above 2 per cent. will also produce necrosis. If the animal be poisoned with gastrotoxic serum the introduction of these solutions into the stomach, in much greater dilution than is necessary to produce necrosis, will markedly increase the lesions. For instance, if a guinea-pig be injected with a dose of the serum and if at the same time a 0·3 to 0·7 per cent. solution of hydrochloric acid, which is itself inactive, be introduced into the stomach the lesions are much more marked than in the control animal. One has here the two protoplasmic poisons combining to produce self-digestion. It is not possible for hyperacidity of the gastric juice ever to reach such a height as to cause ulceration of itself, but it may increase the tendency to such ulceration not by increasing the peptic activity of the gastric juice but by acting as a protoplasmic poison.

course, include the teachers, the caretaker, and any other persons employed on the school premises. It is well known what a high mortality from consumption there is amongst teachers. THE EXPERIMENTAL PRODUCTION OF GASTRIC ULCERATION BY INJECTION OF GASTROTOXIN.[1]

BY CHARLES BOLTON, M.D., D.SC. LOND.,
M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL;
RESEARCH SCHOLAR OF THE GROCERS' COMPANY.

FOR the past five years I have been working upon the pathology of gastric ulceration from an entirely new point of view. Some of my results have already been published in three communications to the Royal Society,[2] and it is my intention to-night to give you a short *résumé* of the main features of the work.

Starting from the facts that specific bacteriolytic sera could be obtained which would destroy the bacteria against which they were formed, and that similarly hæmolytic sera active against red blood corpuscles and in a few instances cytolytic sera had been produced, I conceived the idea of preparing a gastrotoxic serum active against gastric cells, thinking that this would throw light not only upon the phenomena of cytotoxic action but also upon the obscure problem of gastric ulceration. I succeeded in producing such a serum, and without further introduction will describe—first, the method of preparation of the serum; and secondly, the action of the serum: (*a*) on injection into the living animal and (*b*) in the test tube.

I.—*Method of Preparation of the Serum.*

The serum is prepared by injecting the gastric cells of one animal into another, the blood serum of the injected animal becoming poisonous for the kind of gastric cells which have been injected. Three sera have in this way been obtained: (1) By injection of the gastric cells of the guinea-pig into the rabbit; (2) by injection of the gastric cells of the rabbit into the rabbit; and (3) by injection of human gastric cells into the rabbit or the domestic fowl. The human stomach was obtained from operation cases at the hospital, the mucous membrane being scraped off and injected forthwith into the rabbit or fowl. In the other cases the rabbit or guinea-pig, as the case may be, whose gastric cells are to be injected is starved for 24 hours to insure the stomach being empty. The animal is killed, the thoracic viscera are cut out, and a cannula is inserted into the thoracic aorta, through which a stream of sterilised salt solution is run until the abdominal organs are washed quite free from blood. The stomach is cut out, opened, and thoroughly washed. The mucous membrane is then scraped off on a sterilised plate, ground up into an emulsion with salt solution, and injected into the peritoneal cavity of a rabbit. A fresh filtered extract of mucous membrane may be used, but it takes longer to prepare and on the whole does not possess any advantages over the injection of the cells themselves. After seven or ten days the injection is repeated, and when four or five have been given the blood serum of the injected rabbit is found to be highly toxic. The blood is obtained by opening a vessel of the ear, and in this way from 30 to 40 cubic centimetres can easily be obtained each week. The animal may be thus alternately bled and injected for about two months, or more in some cases, after which the toxicity of the serum falls. The blood is whipped and centrifugalised and the serum is always used fresh on the day on which it is obtained. I have immunised more than 150 rabbits in this way during the course of my work.

II.—*Action of the Serum on Injection.*

The following remarks apply to the serum obtained by injecting the rabbit with guinea-pig's stomach cells. No lesion is found in the stomach of the rabbit which has formed the gastrotoxin and no lesion results on injection of the serum into another rabbit. In half an hour after intraperitoneal injection of the serum into a guinea-pig the symptoms of intoxication are well marked and death occurs against which it is formed. Absolute specificity is therefore unknown.

---

[1] A paper read before the Medical Society of London on Feb. 24th, 1908.

[2] Proceedings of the Royal Society: (*a*) vol. lxxiv., p. 135, 1904. (*b*) B. vol. lxxvii., p. 426, 1906; (*c*) B. vol. lxxix., p. 533, 1907.

V.—*Human Gastrotoxin.*

I have been able to show that a serum can be prepared which is active against human gastric cells. All that need be said in this connexion is that the reactions displayed by this serum in the test-tube are absolutely the same as I have already described above.

VI.—*Gastrotoxic Serum produced by Injecting the Rabbit with Rabbit's Gastric Cells.*

The rabbit does not respond very readily to the injection of rabbit's stomach cells, but that it does respond I have been able to prove. The serum so obtained produces no effect upon the rabbit itself nor upon any other rabbit, but it is toxic for the guinea-pig. The symptoms and post-mortem lesions occurring in the guinea-pig as the result of injection of this serum are identical with those which have been described in the case of the guinea-pig-rabbit gastrotoxic serum. The stomach lesions consist of patches of necrosis and ulceration. Previous mixture with rabbit's stomach cells does not render the serum inactive, thereby showing that these cells have no affinities corresponding to those of the immune body acting upon the guinea-pig's tissues. It is more than likely that the rabbit during the absorption of rabbit's tissues, in addition to producing a poison acting upon the guinea-pig's tissues, also forms one acting upon its own, but that this action is prevented by the concomitant formation of an anti-immune body or anti-complement. I have already stated that the normal rabbit produces a hæmolysin for the guinea-pig's corpuscles, which it no doubt forms in response to the absorption of its own tissues. So far as we know the same immunising mechanism, which is concerned in the production of an immune body, is also concerned in the production of an anti-immune body or anti-complement. It seems, therefore, that the formation of an anti-body is the natural consequence of the formation of an immune body. Whether any conditions exist which can upset the formation of the one and leave the other intact, thereby leading to an auto-intoxication, we have yet no experimental data to assist us in deciding.

VII.—*Conclusion.*

It would be premature to apply these results directly to the explanation of human gastric ulcer, but they open up new lines of thought along which to prosecute further research. It is possible that not only certain endogenous but also certain exogenous poisons may be capable of initiating self-digestion through the blood stream and that the production of such lesions may be facilitated not only by hyperacidity of the gastric juice but also by other bodies introduced with the food. It seems that all ulcers produced by digestion of dead or devitalised tissue are essentially acute and, since human gastric ulcer is commonly a chronic malady, it is not so much the actual mode of production which it is necessary to explain as the fact that the ulcer so persistingly refuses to heal. It is possible that this chronicity may depend upon a secondary bacterial infection of the ulcer largely owing to muscular insufficiency, but upon the latter point I hope to be able to speak more definitely at a future date.

LEPROSY: SOME NOTES ON ITS CAUSATION, SYMPTOMS, AND TREATMENT,

BASED ON AN EXPERIENCE OF 152 LEPERS IN THE LEPER JAIL OF THE UNITED PROVINCES, INDIA.[1]

BY THOMAS HUNTER, M.A., B.Sc., M.D. GLASG.,
CAPTAIN, I.M.S.

FROM April 26th, 1905, to Feb. 24th, 1907, in addition to the ordinary duties of a civil surgeon of the Indian Medical Service I held the post of superintendent of the Rai Bareli jail. This jail has a population of about 500 prisoners and in it is a block for leper prisoners. To this block are sent all leper convicts sentenced in the United Provinces of Agra and Oudh. On the day on which I took over charge of the jail the leper block contained 64 lepers and during my term as superintendent 88 lepers were admitted. Out of this total of 152 lepers 24 were for various reasons not examined in detail by me personally. On the records of the balance, 128 lepers, this thesis is based. The total number of cases examined with reference to certain points it will be found is not always the same, as in some of the cases remaining when I took over charge complete notes were not recorded, but the figures given for the various inquiries in all cases refer to series of prisoners without selection.

PART I.—CAUSATION.

The causation of leprosy, in spite of the discovery of the bacillus lepræ, the immediate cause of the symptoms of the disease, remains the subject of discussion. The weight of opinion is that the disease is contagious and that each new case arises by contagion from another case. Opposed to this is the opinion so strongly held by Mr. Jonathan Hutchinson that leprosy arises from the eating of bad fish. More recent than both of these is the suggestion that the disease is conveyed by the bite of the mosquito and the bed bug. The third of these explanations of the origin of leprosy will be little more than mentioned. A letter signed by E. S. Goodhue, Government physician, Hawaii, which appeared in THE LANCET of May 12th, 1906, p. 1347, claimed that bacilli lepræ had been discovered in mosquitoes (*Culex pinguis*) and bed bugs (*Cimex lectularius*) by Dr. W. J. Goodhue, medical superintendent of Molokai Leper Settlement, and suggested that those were the spreading agents. Details have not yet been published, but that the disease should be, even to any great extent, communicated by mosquitoes or bed bugs seems improbable when one considers the comparatively small number of persons affected in a country like India, where mosquitoes and bed bugs are practically of universal distribution, and when one contrasts the prevalence of leprosy with that of malaria, a mosquito-spread disease.

That leprosy is caused by fish-eating is a proposition that has more of the elements of probability, and when supported by the weighty authority of Mr. Hutchinson is one which demands careful consideration. This is no new doctrine in India, for it is a common belief amongst natives of that country that fish food, and especially fish eaten with milk, may bring on leprosy. The Indian Leprosy Commission of 1890-91 considered the question of fish-eating as a possible causative factor, and after examination of several hundred persons affected the commissioners put on record their opinion that there "was no doubt that the consumption of fish was not the cause of leprosy."[2] Mr. Hutchinson was not satisfied with that verdict, however, and having in 1902-03 toured India to investigate at first hand evidence for or against his hypothesis, he has stated in his book published on the subject that "he came away with an assured conviction that whilst there is in India very much which gives strong support to the fish hypothesis there is nowhere anything which controverts it."[3]

Mr. Hutchinson is inclined to refuse due weight to the statistics of the Indian Leprosy Commission and to get behind them by saying that many reasons combined to render open to doubt statements made by lepers about having eaten or not having eaten fish. He points out that the native of India is very apt to answer not according to actual fact but according to fancy or according as he thinks he is wanted to answer; and he thinks the commissioners may have been satisfied with an easy inquiry and that they may have too readily accepted answers given them. The commission report, too, he says, does not specify whether fresh fish or salted fish, fresh-water fish or sea fish, was inquired about, and he believes that confusion from misunderstandings on these points may have falsified their figures. And finally he states that since the commission report the fish hypothesis has embraced "commensal communication" as a possible additional factor in the spread of the disease. In the present inquiry the fish hypothesis has been considered with all these points in mind.

The fish hypothesis as held by Mr. Hutchinson briefly stated is that leprosy is acquired by eating bad fish, but that in some few cases persons who have never eaten fish may have acquired the disease from food contaminated by having been touched by a leper (commensal communication). Uncured, non-salted fish kept till decomposition has set in is not excluded,[4] but according to Mr. Hutchinson

However produced gastric ulcers heal in from 14 to 28 days provided that the health of the body is normal, and that the food, the gastric secretion, and the motor activity of the stomach are also normal. It becomes now necessary to inquire whether any conditions exist which may retard the healing of a gastric ulcer and make it become chronic. This is a subject upon which I am working at the present time, but I have already obtained a few interesting results. I first endeavoured to ascertain whether repeated injection of the gastrotoxic serum would lead to chronic ulceration of the stomach, and I found that far from this being the case the animals developed immunity to the serum. 5 cubic centimetres of the serum heated to 55° C. for half an hour were injected each week and after 10 or 12 injections the animals were protected against a lethal dose of the serum. The serum also had the power of conferring passive immunity upon another guinea-pig, so that when it was injected with a mixture of gastrotoxic serum and immune serum no lesion resulted.

In order to study the effects of abnormal local conditions upon the healing of the ulcer I have used the method of local injection into the stomach wall to produce the ulcer in the first instance. It is quite easy to inject the serum into the anterior or posterior wall or near the cardiac or pyloric orifice, and I have found that ulcers produced in these positions heal with equal rapidity in animals otherwise normal. The effects of hyperacidity of the gastric juice have been tested by feeding the animals in which ulcers had been produced with food soaked in 0·6 per cent. hydrochloric acid solution. This is a high degree of acidity and the guinea-pigs do not like it, but they will eat the food when they are hungry. I have found that on this diet the ulcers heal up quite as quickly as on a normal diet. Hydrochloric acid combined with proteid was also used and the result was the same whether the ulcer was situated in the body or at the pyloric end of the stomach.

With regard to partial neutralisation of the gastric juice I cannot say very much as the experiments are still in progress. The animals are fed on food soaked in 4 per cent. sodium bicarbonate solution. The base of the ulcer is not so clean as when the gastric juice is active and there appears to be more thickening, but I have not yet ascertained whether the healing is delayed. These results are due to the growth of bacteria in the ulcer, which normally should be inhibited by the acid gastric juice.

I will now leave this part of the subject, as my observations on the effects of motor insufficiency are too immature to record and will consider the action of the serum *in vitro*.

III.—*Analysis of the Serum in the Test-tube.*

The serum is capable of bringing about two well-defined reactions *in vitro*:—It is (1) hæmolytic, and (2) contains several precipitins.

1. *Hæmolysin.*—The normal serum of the rabbit is to some extent hæmolytic for guinea-pig's red blood corpuscles; this property is destroyed by heat and the heated serum cannot be re-activated by normal guinea-pig's serum which does not contain a suitable complement. I have been able to demonstrate that the gastrotoxin contains two distinct hæmolysins. The first hæmolysin is an increase of the normal hæmolysin of the rabbit. The increase occurs a few days after the first injection of gastric cells. The second hæmolysin is an artificial product and is distinguished from the former because after heating it can be re-activated by normal guinea-pig's complement. It appears in the blood serum at a later date and is only found in any considerable amount after a second injection of gastric cells has been administered. The hæmolysin is directly produced by absorption of the stomach cells and not of blood corpuscles, because the stomach cells are washed quite free from blood before injection.

This hæmolytic factor takes no part in the production of the gastric necrosis, because it has been already shown that the lesions are not the result of hæmorrhage, and in addition to this if the gastrotoxin be previously mixed with guinea-pig's stomach cells *in vitro* it is thereby rendered incapable of producing lesions on injection, although it can still hæmolyse blood corpuscles. I may here mention that the hæmorrhages produced by a hæmolytic serum are not due to the factor liberating the hæmoglobin from the red corpuscles, but are due to a protoplasmic poison acting upon the capillary wall, the so-called hæmorrhagin.

2. *Precipitins.*—The gastrotoxic serum possesses the property of precipitating the soluble proteid contained in a saline extract of guinea-pig's stomach cells. Such an extract is made by grinding up the cells with normal salt solution in a glass mortar and filtering through a Berkefeld filter. A clear albuminous solution is thus obtained. The addition of a few drops of this solution to the immune serum results in the formation of a well-marked precipitate, which collects at the bottom of the tube, forming a thick deposit. The serum will likewise precipitate albuminous extracts of liver and small intestine cells and the blood serum of the guinea-pig. The strongest action is, however, exerted upon the extract of stomach cells.

I have been able to show that these precipitins are multiple, as they can be separated one by one from solution and during the process of immunisation the different precipitins appear at different times in the blood serum. Removal of the precipitin for the stomach cell proteid, however, destroys the power of the serum to precipitate any other albuminous fluid. The precipitins, therefore, for the various organic extracts of the body are different, but their actions overlap to a considerable extent. Absolute specificity does not exist. These precipitins play no part in the production of the necrotic patches in the stomach, because it is well known that precipitins cause no lesion on injection, the precipitate being soluble in excess of the precipitable substance, so that any precipitate formed would be dissolved by the excess of the animals' fluids present.

3. *Gastrolysin.*—I have never observed solution of the gastric cells in the test-tube. A more or less definite hyaline change occurs in the cells, but I do not wish to lay any great stress on this point at present, because it is only very slight and I have not yet succeeded in determining its nature. I will merely here repeat what I have stated before that there is a definite poison present in the serum which attacks the cells themselves *in vivo*, and that the lesions are brought about by the interaction of an immune body and complement, and further that actual necrosis of the cell does not result, but merely a functional change rendering it susceptible to the action of the gastric juice.

IV.—*Specificity of the Gastrotoxin.*

The specificity has been tested by ascertaining (1) whether the gastrotoxin has the power of acting upon other tissues; (2) whether sera formed against other tissues can act upon gastric cells; and (3) what power various tissues possess of removing the gastrotoxin from solution by combining with it, thus rendering the serum inactive.

1. *Action of the gastrotoxin upon other tissues.*—I have already stated that the serum can hæmolyse red blood corpuscles and precipitate the albuminous extracts of other tissues in the test-tube. Although no gross lesion can be found *in vivo* apart from those of the stomach, the facts that the animal is killed and that it exhibits marked symptoms of intoxication are quite sufficient to show that the action is not limited to the stomach.

2. *Action of other sera.*—Three sera have been used—hepatotoxin, enterotoxin, and hæmolysin, formed respectively by injecting liver cells, intestine cells, and red blood corpuscles.

Each serum on injection produces gastric lesions of the same character as those produced by the gastrotoxin, but of a much less pronounced nature generally. I have been able to show that this is likewise a process of *self-digestion*, and that the various acids mentioned above on introduction into the stomach increase the lesions. Hepatotoxin and enterotoxin are hæmolytic in the test-tube and they contain multiple precipitins which act most powerfully on the tissues against which they are formed.

3. *Removal of the gastrotoxin by various tissues.*—The serum was exposed to the action of various cells of the guinea-pig previously to injection. Gastric cells are able to remove completely the poison and to render the serum inactive. Liver and intestinal cells can do so to some extent. If the serum is a weak one the action may be destroyed, but otherwise it is merely reduced. Red blood corpuscles are also able to some extent to remove the poison. The hæmolytic factor of the gastrotoxin can be removed from solution by liver and intestinal cells and red blood corpuscles, but gastric cells, although they render the serum inactive *in vivo*, are unable to combine with the hæmolysin and to prevent its action *in vitro*. Rabbit's tissues are absolutely unable to affect the action of the serum. It is probably the case that all the cytotoxic sera are of the same nature, and that each serum contains poisons which will attack all the cells of the body but more especially the cells

against which it is formed. Absolute specificity is therefore unknown.

V.—*Human Gastrotoxin.*

I have been able to show that a serum can be prepared which is active against human gastric cells. All that need be said in this connexion is that the reactions displayed by this serum in the test-tube are absolutely the same as I have already described above.

VI.—*Gastrotoxic Serum produced by Injecting the Rabbit with Rabbit's Gastric Cells.*

The rabbit does not respond very readily to the injection of rabbit's stomach cells, but that it does respond I have been able to prove. The serum so obtained produces no effect upon the rabbit itself nor upon any other rabbit, but it is toxic for the guinea-pig. The symptoms and post-mortem lesions occurring in the guinea-pig as the result of injection of this serum are identical with those which have been described in the case of the guinea-pig-rabbit gastrotoxic serum. The stomach lesions consist of patches of necrosis and ulceration. Previous mixture with rabbit's stomach cells does not render the serum inactive, thereby showing that these cells have no affinities corresponding to those of the immune body acting upon the guinea-pig's tissues. It is more than likely that the rabbit during the absorption of rabbit's tissues, in addition to producing a poison acting upon the guinea-pig's tissues, also forms one acting upon its own, but that this action is prevented by the concomitant formation of an anti-immune body or anti-complement. I have already stated that the normal rabbit produces a hæmolysin for the guinea-pig's corpuscles, which it no doubt forms in response to the absorption of its own tissues. So far as we know the same immunising mechanism, which is concerned in the production of an immune body, is also concerned in the production of an anti-immune body or anti-complement. It seems, therefore, that the formation of an anti-body is the natural consequence of the formation of an immune body. Whether any conditions exist which can upset the formation of the one and leave the other intact, thereby leading to an auto-intoxication, we have yet no experimental data to assist us in deciding.

VII.—*Conclusion.*

It would be premature to apply these results directly to the explanation of human gastric ulcer, but they open up new lines of thought along which to prosecute further research. It is possible that not only certain endogenous but also certain exogenous poisons may be capable of initiating self-digestion through the blood stream and that the production of such lesions may be facilitated not only by hyperacidity of the gastric juice but also by other bodies introduced with the food. It seems that all ulcers produced by digestion of dead or devitalised tissue are essentially acute and, since human gastric ulcer is commonly a chronic malady, it is not so much the actual mode of production which it is necessary to explain as the fact that the ulcer so persistingly refuses to heal. It is possible that this chronicity may depend upon a secondary bacterial infection of the ulcer largely owing to muscular insufficiency, but upon the latter point I hope to be able to speak more definitely at a future date.

Devonshire-street, W.

LEPROSY: SOME NOTES ON ITS CAUSATION, SYMPTOMS, AND TREATMENT,

BASED ON AN EXPERIENCE OF 152 LEPERS IN THE LEPER JAIL OF THE UNITED PROVINCES, INDIA.[1]

By THOMAS HUNTER, M.A., B.Sc., M.D. GLASG.,
CAPTAIN, I.M.S.

FROM April 26th, 1905, to Feb. 24th, 1907, in addition to the ordinary duties of a civil surgeon of the Indian Medical Service I held the post of superintendent of the Rai Bareli jail. This jail has a population of about 500 prisoners and in it is a block for leper prisoners. To this block are sent all leper convicts sentenced in the United Provinces of Agra and Oudh. On the day on which I took over charge of the jail the leper block contained 64 lepers and during my term as superintendent 88 lepers were admitted. Out of this total of 152 lepers 24 were for various reasons not examined in detail by me personally. On the records of the balance, 128 lepers, this thesis is based. The total number of cases examined with reference to certain points it will be found is not always the same, as in some of the cases remaining when I took over charge complete notes were not recorded, but the figures given for the various inquiries in all cases refer to series of prisoners without selection.

PART I.—CAUSATION.

The causation of leprosy, in spite of the discovery of the bacillus lepræ, the immediate cause of the symptoms of the disease, remains the subject of discussion. The weight of opinion is that the disease is contagious and that each new case arises by contagion from another case. Opposed to this is the opinion so strongly held by Mr. Jonathan Hutchinson that leprosy arises from the eating of bad fish. More recent than both of these is the suggestion that the disease is conveyed by the bite of the mosquito and the bed bug. The third of these explanations of the origin of leprosy will be little more than mentioned. A letter signed by E. S. Goodhue, Government physician, Hawaii, which appeared in THE LANCET of May 12th, 1906, p. 1347, claimed that bacilli lepræ had been discovered in mosquitoes (*Culex pinguis*) and bed bugs (*Cimex lectularius*) by Dr. W. J. Goodhue, medical superintendent of Molokai Leper Settlement, and suggested that those were the spreading agents. Details have not yet been published, but that the disease should be, even to any great extent, communicated by mosquitoes or bed bugs seems improbable when one considers the comparatively small number of persons affected in a country like India, where mosquitoes and bed bugs are practically of universal distribution, and when one contrasts the prevalence of leprosy with that of malaria, a mosquito-spread disease.

That leprosy is caused by fish-eating is a proposition that has more of the elements of probability, and when supported by the weighty authority of Mr. Hutchinson is one which demands careful consideration. This is no new doctrine in India, for it is a common belief amongst natives of that country that fish food, and especially fish eaten with milk, may bring on leprosy. The Indian Leprosy Commission of 1890–91 considered the question of fish-eating as a possible causative factor, and after examination of several hundred persons affected the commissioners put on record their opinion that there "was no doubt that the consumption of fish was not the cause of leprosy."[2] Mr. Hutchinson was not satisfied with that verdict, however, and having in 1902–03 toured India to investigate at first hand evidence for or against his hypothesis, he has stated in his book published on the subject that "he came away with an assured conviction that whilst there is in India very much which gives strong support to the fish hypothesis there is nowhere anything which controverts it."[3]

Mr. Hutchinson is inclined to refuse due weight to the statistics of the Indian Leprosy Commission and to get behind them by saying that many reasons combined to render open to doubt statements made by lepers about having eaten or not having eaten fish. He points out that the native of India is very apt to answer not according to actual fact but according to fancy or according as he thinks he is wanted to answer; and he thinks the commissioners may have been satisfied with an easy inquiry and that they may have too readily accepted answers given them. The commission report, too, he says, does not specify whether fresh fish or salted fish, fresh-water fish or sea fish, was inquired about, and he believes that confusion from misunderstandings on these points may have falsified their figures. And finally he states that since the commission report the fish hypothesis has embraced "commensal communication" as a possible additional factor in the spread of the disease. In the present inquiry the fish hypothesis has been considered with all these points in mind.

The fish hypothesis as held by Mr. Hutchinson briefly stated is that leprosy is acquired by eating bad fish, but that in some few cases persons who have never eaten fish may have acquired the disease from food contaminated by having been touched by a leper (commensal communication). Uncured, non-salted fish kept till decomposition has set in is not excluded,[4] but according to Mr. Hutchinson

However produced gastric ulcers heal in from 14 to 28 days provided that the health of the body is normal, and that the food, the gastric secretion, and the motor activity of the stomach are also normal. It becomes now necessary to inquire whether any conditions exist which may retard the healing of a gastric ulcer and make it become chronic. This is a subject upon which I am working at the present time, but I have already obtained a few interesting results. I first endeavoured to ascertain whether repeated injection of the gastrotoxic serum would lead to chronic ulceration of the stomach, and I found that far from this being the case the animals developed immunity to the serum. 5 cubic centimetres of the serum heated to 55° C. for half an hour were injected each week and after 10 or 12 injections the animals were protected against a lethal dose of the serum. The serum also had the power of conferring passive immunity upon another guinea-pig, so that when it was injected with a mixture of gastrotoxic serum and immune serum no lesion resulted.

In order to study the effects of abnormal local conditions upon the healing of the ulcer I have used the method of local injection into the stomach wall to produce the ulcer in the first instance. It is quite easy to inject the serum into the anterior or posterior wall or near the cardiac or pyloric orifice, and I have found that ulcers produced in these positions heal with equal rapidity in animals otherwise normal. The effects of hyperacidity of the gastric juice have been tested by feeding the animals in which ulcers had been produced with food soaked in 0·6 per cent. hydrochloric acid solution. This is a high degree of acidity and the guinea-pigs do not like it, but they will eat the food when they are hungry. I have found that on this diet the ulcers heal up quite as quickly as on a normal diet. Hydrochloric acid combined with proteid was also used and the result was the same whether the ulcer was situated in the body or at the pyloric end of the stomach.

With regard to partial neutralisation of the gastric juice I cannot say very much as the experiments are still in progress. The animals are fed on food soaked in 4 per cent. sodium bicarbonate solution. The base of the ulcer is not so clean as when the gastric juice is active and there appears to be more thickening, but I have not yet ascertained whether the healing is delayed. These results are due to the growth of bacteria in the ulcer, which normally should be inhibited by the acid gastric juice.

I will now leave this part of the subject, as my observations on the effects of motor insufficiency are too immature to record and will consider the action of the serum *in vitro.*

III.—*Analysis of the Serum in the Test-tube.*

The serum is capable of bringing about two well-defined reactions *in vitro*:—It is (1) hæmolytic, and (2) contains several precipitins.

1. *Hæmolysin.*—The normal serum of the rabbit is to some extent hæmolytic for guinea-pig's red blood corpuscles; this property is destroyed by heat and the heated serum cannot be re-activated by normal guinea-pig's serum which does not contain a suitable complement. I have been able to demonstrate that the gastrotoxin contains two distinct hæmolysins. The first hæmolysin is an increase of the normal hæmolysin of the rabbit. The increase occurs a few days after the first injection of gastric cells. The second hæmolysin is an artificial product and is distinguished from the former because after heating it can be re-activated by normal guinea-pig's complement. It appears in the blood serum at a later date and is only found in any considerable amount after a second injection of gastric cells has been administered. The hæmolysin is directly produced by absorption of the stomach cells and not of blood corpuscles, because the stomach cells are washed quite free from blood before injection.

This hæmolytic factor takes no part in the production of the gastric necrosis, because it has been already shown that the lesions are not the result of hæmorrhage, and in addition to this if the gastrotoxin be previously mixed with guinea-pig's stomach cells *in vitro* it is thereby rendered incapable of producing lesions on injection, although it can still hæmolyse blood corpuscles. I may here mention that the hæmorrhages produced by a hæmolytic serum are not due to the factor liberating the hæmoglobin from the red corpuscles, but are due to a protoplasmic poison acting upon the capillary wall, the so-called hæmorrhagin.

2. *Precipitins.*—The gastrotoxic serum possesses the property of precipitating the soluble proteid contained in a saline extract of guinea-pig's stomach cells. Such an extract is made by grinding up the cells with normal salt solution in a glass mortar and filtering through a Berkefeld filter. A clear albuminous solution is thus obtained. The addition of a few drops of this solution to the immune serum results in the formation of a well-marked precipitate, which collects at the bottom of the tube, forming a thick deposit. The serum will likewise precipitate albuminous extracts of liver and small intestine cells and the blood serum of the guinea-pig. The strongest action is, however, exerted upon the extract of stomach cells.

I have been able to show that these precipitins are multiple, as they can be separated one by one from solution and during the process of immunisation the different precipitins appear at different times in the blood serum. Removal of the precipitin for the stomach cell proteid, however, destroys the power of the serum to precipitate any other albuminous fluid. The precipitins, therefore, for the various organic extracts of the body are different, but their actions overlap to a considerable extent. Absolute specificity does not exist. These precipitins play no part in the production of the necrotic patches in the stomach, because it is well known that precipitins cause no lesion on injection, the precipitate being soluble in excess of the precipitable substance, so that any precipitate formed would be dissolved by the excess of the animals' fluids present.

3. *Gastrolysin.*—I have never observed solution of the gastric cells in the test-tube. A more or less definite hyaline change occurs in the cells, but I do not wish to lay any great stress on this point at present, because it is only very slight and I have not yet succeeded in determining its nature. I will merely here repeat what I have stated before that there is a definite poison present in the serum which attacks the cells themselves *in vivo*, and that the lesions are brought about by the interaction of an immune body and complement, and further that actual necrosis of the cell does not result, but merely a functional change rendering it susceptible to the action of the gastric juice.

IV.—*Specificity of the Gastrotoxin.*

The specificity has been tested by ascertaining (1) whether the gastrotoxin has the power of acting upon other tissues; (2) whether sera formed against other tissues can act upon gastric cells; and (3) what power various tissues possess of removing the gastrotoxin from solution by combining with it, thus rendering the serum inactive.

1. *Action of the gastrotoxin upon other tissues.*—I have already stated that the serum can hæmolyse red blood corpuscles and precipitate the albuminous extracts of other tissues in the test-tube. Although no gross lesion can be found *in vivo* apart from those of the stomach, the facts that the animal is killed and that it exhibits marked symptoms of intoxication are quite sufficient to show that the action is not limited to the stomach.

2. *Action of other sera.*—Three sera have been used—hepatotoxin, enterotoxin, and hæmolysin, formed respectively by injecting liver cells, intestine cells, and red blood corpuscles.

Each serum on injection produces gastric lesions of the same character as those produced by the gastrotoxin, but of a much less pronounced nature generally. I have been able to show that this is likewise a process of self-digestion, and that the various acids mentioned above on introduction into the stomach increase the lesions. Hepatotoxin and enterotoxin are hæmolytic in the test-tube and they contain multiple precipitins which act most powerfully on the tissues against which they are formed.

3. *Removal of the gastrotoxin by various tissues.*—The serum was exposed to the action of various cells of the guinea-pig previously to injection. Gastric cells are able to remove completely the poison and to render the serum inactive. Liver and intestinal cells can do so to some extent. If the serum is a weak one the action may be destroyed, but otherwise it is merely reduced. Red blood corpuscles are also able to some extent to remove the poison. The hæmolytic factor of the gastrotoxin can be removed from solution by liver and intestinal cells and red blood corpuscles, but gastric cells, although they render the serum inactive *in vivo*, are unable to combine with the hæmolysin and to prevent its action *in vitro*. Rabbit's tissues are absolutely unable to affect the action of the serum. It is probably the case that all the cytotoxic sera are of the same nature, and that each serum contains poisons which will attack all the cells of the body but more especially the cells

food is eaten not with spoon, fork, or knife, but with the fingers directly. If then commensal communication is to be accepted as the explanation of how the disease has been acquired in many cases where the contamination of food must have been remote and of the slightest degree, such as cases where no acquaintance with lepers existed, individuals whose food is habitually exposed to such contamination should rarely escape the disease and communication of the disease from a leprous husband to his healthy wife should be the rule.

The prisoners' histories were here useless but the Report of the Indian Leprosy Commission, pp. 308–310, gives some figures directly bearing on the point. The Commission examined 381 couples of each of which one member was a leper. All these couples had lived together for at least five years and in 25 cases only was the disease traced from one member to the other. Of these 25 the Commissioners, for reasons not stated, eliminated six, leaving the number of communications from husband to wife or *vice versâ* at 19 or 4·9 per cent. Unfortunately, the proportion in which the leper member of the couple was the husband is not stated but it may be safely assumed that this was more often the case. These figures make it impossible to accept commensal communication as the mode of infection in non-fish-eaters knowing no other lepers.

The most general present-day opinion seems to be that leprosy is contagious. The histories of the leper prisoners are not full enough to give much evidence for or against the contagiousness of leprosy. Inquiries, however, were regularly made about the existence of leprosy in relatives, associates, or acquaintances, with the results tabulated below:—

Total number of lepers.	Leprosy in family.	Leprosy in associates.	Leprosy in acquaintances.	Knew no leper out of jail.
136	39	29	14	54

The absolute accuracy of the facts denoted by these figures, of course, cannot be vouched for. It is believed that they are true so far as the prisoners themselves knew, but naturally in a disease like leprosy which may exist for some time with little or no prominent symptoms the probabilities are that in an endemic centre such as India there are persons who are lepers, though this is not known to their friends and probably not even to themselves. Granting, then, that such cases may exist and admitting for the sake of argument that, as is suggested by Dr. R. Sinclair Black in his paper in THE LANCET of April 28th, 1906 (p. 1167), these cases may be "sources of infection," the error resulting from their omission is certain to be much smaller than the error in the other direction resulting from the fact that between prisoners on the one hand and relatives, associates, and acquaintances on the other it was impossible to determine priority of infection.

To return to the figures, out of 136 lepers 68 had leper relatives or associates, 14 knew a leper or lepers of other castes, and 54 knew no other leper. At a first glance this looks like a strong support of the contagiousness of the disease; the 54 who knew no other leper are apt to be lost sight of in the 68 who had some history of association with lepers. But this 68 really proves little. To support the theory that the disease is contagious what is wanted is the number of persons who have associated with lepers and of these the number who have acquired the disease. Such an inquiry was beyond the scope of this thesis.

The doctrine of the contagionists as enunciated by Professor Neisser at the International Congress on Dermatology, 1904,[8] is that the "disease is contagious and spread exclusively by lepers." A certain proportion of cases occur in individuals who have associated with other persons affected and extension by contagion might explain these; while cases, like the often-quoted one reported by Dr. Benson in the *Dublin Journal of Medical Science* for 1877,[9] seem to admit of no other explanation than that the disease spread by contagion to a healthy person from a leper. But the exact mode of diffusion remains undetermined, though in all such cases a long and intimate association seems necessary.

A certain other proportion of the cases of leprosy, however, arises where inquiries fail to trace a pre-existing case of the disease from which contagion could have been acquired. Of 136 lepers in Rai Bareli jail 54 it was shown were in this group. If the theory of the contagionists be accepted it must be presumed that such cases of leprosy acquired the disease during some chance unknown, and therefore in most cases at least during slight and fleeting association with a leper, unlike the long and intimate intercourse which seems to have been necessary in cases where the spread by contagion has been most clearly established. If such a presumption is passed it must be admitted that leprosy, at times, at least, is bound to be a very easily communicable malady. But all the known facts of the case are in conflict with this, and it is inconceivable that a very easily communicable disease which is very rarely cured, to restrict which practically no measures of segregation are practised, and of the sufferers from which very few have recourse to treatment, should show, as does leprosy, a steady decrease amongst the general population.[10] Again, occasional cases of leprosy reach Britain from countries where the disease is comparatively common but no danger is apprehended that these cases will act as foci for the extension of the disease in this country. Leprosy cannot be looked on as at all easily communicable and cases like the 54 above still await explanation.

One more point in this connexion is of the number of persons in intimate association with lepers the small proportion which actually acquires the disease. The Indian Leprosy Commission[11] investigated 104 cases of individuals who had long associated with lepers and of these only one, or possibly two, had acquired the disease. The records of the Rai Bareli jail give similar evidence. No warder in the institution has become infected. A dresser has worked amongst the lepers for nine years dressing sores daily, and although till recently he exercised no special precautions this man has not contracted the disease. And several cases are on record of prisoners admitted to the leper jail as doubtful lepers or under wrong diagnosis who remained in the leper block for long periods and who, finally, were transferred without having acquired the disease.

These facts do not negative contagion as a factor in the spread of the disease but they indicate that if the disease is a contagious one in addition to the actual contagium itself other conditions of not less importance are requisite before the contagium can act. What these conditions are remain undetermined. In the present state of our knowledge comparison with tuberculosis seems to provide the clearest conception of the method of diffusion of leprosy. In both diseases there seem to be well established examples of extension by direct contagion, in both in addition to the actual presence of the contagium vivum other conditions seem requisite before the disease can develop, and in both a certain number of cases arise so completely independently of other cases that the only satisfactory explanation which presents itself is a more or less general distribution of the respective bacilli (of the bacillus lepræ probably only in endemic areas) which remain capable, given the necessary conditions, of giving rise to the disease.

PART II.—SYMPTOMS.

Two distinct forms of the disease have been recognised, the maculo-anæsthetic and the nodular, and well-marked cases of these offer a striking contrast in appearance. But many lepers present the symptoms of both of these cardinal types, and therefore a grouping into three classes, maculo-anæsthetic, nodular, and mixed, has been made. This is the usual classification. Hansen, however, adopts two groups only, including in the nodular all mixed cases. The maculo-anæsthetic type is the less acute form of the disease and a noteworthy feature of the cases in Rai Bareli jail was the comparatively large number of the maculo-anæsthetic type.

[8] THE LANCET, Nov. 19th, 1904, p. 1453.

[9] A man whose brother came home from abroad a leper acquired the disease after having lived with the brother one and a half years and after the brother's death wore his clothes.

[10] The following table is taken from the Census Report of the United Provinces for 1906:—

Census year.	Leprosy totals.	Number per 10,000.	
		Males.	Females.
1881	17,822	6·30	1·59
1891	16,895	5·74	1·30
1901	11,328	3·59	1·08

[11] Indian Leprosy Commission Report, p. 321.

badly cured fish is the chief cause of the disease.[5] The evidence for or against uncured fish, cured fish, and contaminated food as causes of the disease will be taken up separately. In the inquiry on these points the following method was adopted. On admission to the jail the lepers were examined by me personally. When each man was questioned about having eaten fish it was made clear to him that the inquiry referred to fish of any kind eaten at any time and not only to the habitual use of fish as an article of diet. Each man, moreover, was examined apart from the other prisoners. The facts thus elicited were recorded in each man's history and it is worthy of note that a subsequent inquiry made to check these original entries detected only one discrepancy. This subsequent inquiry was conducted towards the end of my term as superintendent and was completed on one afternoon. No previous intimation of it was given to anyone, warder or prisoner. Each leper in the jail on that particular day—the total was 63—was taken apart from the others and questioned on the subject of fish-eating with the same care as has been noted above. No one knew beforehand the purpose for which he was taken out of sight and earshot of the other prisoners, and having been questioned no prisoner was allowed to return or communicate with those waiting for examination. The only man whose second statement did not agree with that made on admission was a Brahman who on admission said he might have eaten fish as a child and at the second inquiry said he had never eaten fish.

The examination of the prisoners brought out the fact that fish was extensively used as an article of diet throughout the United Provinces, but that the fish eaten was fresh fish. This is easily procurable at most places from river or tank at some season of the year and apparently is a common article of diet with all castes except Brahmans and Bannias. Of 128 leper prisoners examined in Rai Bareli jail 34 (or 26·60 per cent.) denied having eaten fish at any time. As a means of comparison a series of 128 consecutive prisoners of the ordinary jail—i.e., non-lepers—were questioned on the point with the same precautions as had been exercised with the lepers, and of these 35 (or 26·66 per cent.) denied ever having eaten fish. The proportions of fish-eaters among lepers and non-lepers therefore were practically the same.

With a view to comparing lepers and non-lepers as far as fish-eating goes another plan was adopted. Amongst Hindus the two castes whose tenets most strictly enjoin vegetarianism are Brahmans and Bannias. Mr. Hutchinson would doubt the veracity of a Brahman or a Bannia who asserted that he had never eaten fish; but there can be no doubt about it that it is distinctly exceptional to find in the United Provinces a man of either of those castes who is not a strict vegetarian. If fish-eating then is the cause of leprosy one would expect that the proportion of Brahmans and Bannias amongst lepers would be less than the proportion of those castes amongst the general population; and similarly that the proportion of Brahman and Bannia leper prisoners to the total leper prisoners would be less than the proportion of Brahman and Bannia non-leper prisoners to the total non-leper prisoners of the ordinary jail.

The admissions to the jail for the period April 26th, 1905, to the end of November, 1906, were scrutinised and it was found that this difference did not exist. In 84 lepers admitted there were 11 Brahmans and Bannias (or 13·10 per cent.), whereas in 1234 non-leper admissions Brahmans and Bannias totalled 164 (or 13·29 per cent.). The difference is nominal. The figures of the 1901 Census of the United Provinces give still more convincing evidence of this kind, and a few extracted from p. 206 of the Census Report are here given.

Lepers per 10,000.

	Males.		Females.
General population	3·59	....	1·08
Brahmans	4·05	....	1·16
Bannias	3·41	....	0 95
Châmars (a very low caste who eat anything)	2·89	....	0 93

"The highest caste in the Hindus—viz., the Brahmans—shows a larger proportion than any of the others."[6]

The available evidence, then, as derived from the above facts is against the hypothesis that leprosy in India is caused by eating uncured fish.

If facts observed in the United Provinces militate against the doctrine that the eating of bad fish not cured or dried is the cause of leprosy, much more so do they militate against the doctrine that eating badly cured fish may cause the disease. For some time no evidence could be obtained of the use in the United Provinces of anything in the nature of cured or dried fish at all. Prisoners and jail staffs, the latter educated Indians, except a few men who had visited Calcutta or Bombay, did not know of such an article of diet. Towards the end of the period of inquiry, however, it was found that certain prawns (jhinga), generally eaten fresh, were occasionally sun-dried and thus preserved for a few months. For the purpose of this inquiry these dried prawns were taken as cured fish. Even they, however, are very little used and many persons had never heard of them being preserved by drying. Inquiries were made from many educated Indians of all classes, and no other article of diet coming into the category of dried or salted fish could be discovered to be used in the United Provinces—excepting, of course, tinned fish imported for, and exclusively used by, Europeans. When the facts about the prawns were learned all the lepers then in the jail, 61 in number, were again carefully questioned, and this time direct questions were made about dried prawns. Of the 61 lepers 48 had never eaten cured prawns and 13 had eaten them at some time or other, most of these very occasionally, and as a rule only once or twice in their lives.

In getting at these figures the same precautions were adopted as have been noted above, and, moreover, of the 48 who had never eaten the dried prawns many readily admitted having eaten fresh fish. The figures are believed to be accurate. To compare lepers and non-lepers on this point, 61 consecutive non-leper prisoners of the ordinary jail were similarly questioned; of these, 11 admitted having at some time or other eaten dried prawns, while 50 had never tasted them. The difference is on the side of the hypothesis: but in view of the proportion of the lepers who had never eaten the dried crustacean it may be neglected, and it can be confidently asserted that there is no evidence in favour of the idea that the eating of bad preserved prawns is the cause of leprosy. It might be said that those who had never eaten prawns had acquired the disease by eating bad uncured fish and *vice versâ*. This possibility was examined. Of the 49 lepers who had never eaten cured prawns 13 had also never eaten fish and all the non-fish-eaters were also men who had never eaten prawns of any kind, fresh or cured. The general conclusion then from these facts is that in the United Provinces of Agra and Oudh no circumstantial evidence has been discovered supporting the hypothesis that leprosy as met with in that part of India is due to the eating of bad fish cured or uncured.

To explain cases where fish-eating cannot possibly have been the cause the fish hypothesis has lately embraced "commensal communication"—communication of the disease from a leper to a healthy person by that person eating food touched by the leper. This, which is really a restricted form of contagion, will now be considered in view of the histories given by the Rai Bareli lepers. The proportion of the leper prisoners in which there was no history of fish-eating, given above as 26·60 per cent., may be taken as at least approximately accurate. That such a large percentage acquired the disease through eating food contaminated by contact with a leper apparently even Mr. Hutchinson would think improbable.[7] The actual number of lepers believed never to have eaten fish was 34 and to 16 of these leper prisoners no other leper was known before admission to the jail. An hypothesis which declares the disease not contagious but which requires that out of 128 persons affected 16 acquired the disease by eating food in some way contaminated by a leper though no leper whatever was known to them and though the proportion of population affected is less than 3 per 10,000 cannot be said to be well substantiated.

But even more fatal to the idea of commensal communication than these figures is the infrequency of the communication from husband to wife. In India husbands and wives do not eat together. In rich, well-appointed households the husbands have their food cooked apart from that of their wives and eat it apart; but in poorer households the husbands eat first and after them from the same vessels the wives eat what is left. This latter arrangement holds in by far the majority of cases. Moreover, in India by all classes breaking down and ulcerating. This man's face and body while this process was going on resembled those of a person suffering from small-pox. He was released after the condition had passed its worst and with good general health.

PART III.—TREATMENT.

In the jail all lepers were brought under excellent hygienic conditions. Good food, suitable clothing, enforced cleanliness, abundance of fresh air, and appropriate light labour were the lot of all. Sores and ulcers were kept clean and any little surgical measure deemed necessary was done. In addition to these general measures medicinal treatment of some kind was practised with most of the prisoners. The medicines tried were chaulmoogra oil, gurjun oil, salol, and salicylic acid ointment, each in selected groups. The conclusion come to was that none of these remedies was followed by any special benefit, and towards the end of the period of observation their use was abandoned for a simple symptomatic line of treatment. In December, 1906, and January, 1907, a trial was made of subcutaneous injections of 30 per cent. emulsions of iodoform in olive oil by which a German colonial officer, Dr. Diesing, was reported to have had success. Injections of four cubic centimetres of this emulsion were given to six selected cases. After 12 injections the practice was suspended to await results. No influence on the disease was detected up to the end of February, 1907. During the period of observation nine lepers died and 94 were released—22 with the symptoms alleviated, 21 with the symptoms more pronounced, and 51 practically in the same condition as on admission. In two of these which improved no symptoms could be found of the disease at all at release. In the majority of the cases it was recorded that the general health had improved during the stay in jail, this being not infrequently noted even in cases in which the special symptoms of leprosy seemed to have increased. Of the 94 released, 63 had gained in weight (average gain 9·46 pounds), 30 had lost weight (average loss 6·43 pounds), and six showed no change. The average duration of confinement of the 94 was 12·41 months. Of the nine cases who died only one was a maculo-anæsthetic leper. He was stated to have had the disease for 16½ years and had been in the leper jail for 13½ years. The others were mixed cases. The cause of death in all was some intercurrent affection—diarrhœa in six, tubercle of lungs in two, and gangrene in one. In all the leprosy was of many years' duration[18] and the prisoner was markedly debilitated by it.

AORTIC ANEURYSMS; SUDDEN DEATHS; THE CAPACITY OF THE PERICARDIUM.

BY HERBERT A. SMITH, M.D. DURH., M.R.C.S. ENG., L.R.C.P. EDIN.

> "I say that aneurysm is cured by rest and not by the surgeon!"—
> *John Hilton.*

THE mystery of sudden death commands interest, clinical, physiological, and forensic, and the last especially—the chemical, toxic, and traumatic causes—have a wide range of uncertainty, for the objective appearances of death do not always correspond with the classical modes thereof as given by Bichât, and with pathological causes there is often doubt. It is said by Virchow[1] "to be almost absolutely certain that the two most important kinds of death, asphyxia and paralysis, occur from overfilling of the right and left ventricles of the heart," yet in the following case both these cavities were found empty. Vivian Poore[2] says that sudden death obtains (1) by failure of blood, as in hæmorrhage, rupture of aneurysms, &c.; (2) failure of heart action through systemic, valvular, or thrombotic causes; and (3) failure of respiration through central or peripheral causes, that when the lungs cease first you get cyanosis and engorgement of the right heart and systemic veins, and when the circulation stops first you get pallor from a nearly empty left heart.

CASE 1.—On March 5th, 1908, I was summoned to a man in a fit. On arrival two minutes later he was dead; he had been pruning roses and suddenly feeling faint and giddy he fell to the ground. I found marked cyanosis, blueness of the lips and cheeks, and a congested venous state of the neck. The mouth was open, showing a protruding tongue, a condition suggesting some pressure on the venous return. Did the lungs cease before the heart? On making a necropsy (before an inquest) I found, after removing the front of the sternum and ribs to the subclavicular line, a distended viscus ready to burst; it was the pericardium pressing the diaphragm downwards and occupying a wide pulmonary area; on opening it 14 ounces of serum were baled out and then five ounces of soft black blood clot. The chambers of the heart, save a long thin clot in the right auricle, were empty and the valves were intact and competent, but an aneurysm of the ascending aorta (saccular) of the size of a walnut was found, the seat of rupture having a stellate appearance. The inner coat was stretched and torn and the other coats were soft, fatty, and friable. The intima right down to the thoracic aorta was riddled with areas of atheroma and calcareous plates and granules. There was no illness, no complaint, no lapse of work; yet the disease proceeded without let in a man of fine physique. It is said by Broadbent that "the favourite site of an aneurysm to rupture is through the unsupported sinuses of Valsalva," the intrapericardial portion of the ascending aorta, and that sudden death may occur without previous physical signs.[3] The lining of the pericardium common to the aorta and pulmonary artery in a single tube favours early rupture of the aneurysmal sac, yet with the atheromatous changes, the fact that no symptom is felt, no sign complained of, is noteworthy.

Some years ago a woman was admitted into the Middlesex Hospital for obscure pains in the chest and stabbing sensations, and gradually advancing pallor, faintness, and giddiness led to death. A post-mortem examination was made, and as the heart was taken out the pathologist pricked his finger by a needle which had traversed the œsophagus, trachea, pericardium, and the ascending aorta through a sinus of Valsalva, and the point of which was in the pericardium. Some 10 ounces of blood were found; trickling of blood alongside the needle had led to rupture and fatal flow.

Men live on the brink of a precipice. The cone of the fatal clot, the flimsy film, the flaw within the tube, and the fragile vessel or sac gives way without a signal.

CASE 2.—A city merchant whose life had been one of constant activity and excitement was under my care for aneurysm of the arch of the aorta for 11 years. During this time he presented most of the cardinal features of the disease and the saccular tumour grew to the size of a pear, eroding the sternum and extending the skin into a cone, yet strengthened by newly organised tissue. He kept his bed at first on and off for three months at a time for two years and took as much as two pounds of iodide of potassium with little fluid. He afterwards went daily to business, smoked two or three cigars, and enjoyed life. At 55 years of age he went for a winter cruise in the Mediterranean and coming home died somewhat suddenly from acute double pneumonia. The aneurysm had compressed behind the pulmonary artery and bronchial tubes and laterally had led to pulmonary condensation and absorption, thus favouring pneumonia.

CASE 3.—A few years ago I was summoned in the early morning to see a man, aged 56 years, who had fallen to the floor while entering a bath. I found him dead. There was marked pallor of the upper, and cyanosis of the lower, half of the face. A post-mortem examination elicited a thoracic aneurysm of the size of a tennis-ball which had absorbed a corresponding portion of lung and had ruptured into the posterior left mediastinum; it was saccular, occupying the costo-vertebral trough over the eighth and ninth ribs. The arterial opening was small and the site was favourable for support and for that side-flow or oblique eddy that favours coagulation. The right ventricle contained much blood clot. The sac wall was brittle, laminated, and lined with old and organising clot. Three months before Dr. T. T. Whipham had seen the case for backache, dyspnœa, and pleurodynia and had merely suspected an aneurysm, which had grown with great rapidity.

The early diagnosis of aneurysm by the x rays becomes important. Dr. David Arthur tells me that by its means aneurysms can be diagnosed from the merest budding to the point of rupture and that the time of giving way can be predicted with nicety outside the body. Moreover, by Hotznecht's process—the anterior right oblique position—the smallest aneurysm can be seen and shadowed, but the rate of

In 149 lepers there were 85 of this class, 11 nodular and 53 mixed, equivalent to a percentage proportion of—

Maculo-anæsthetic.	Nodular.	Mixed.
57·05	7·38	35·57

These proportions are very similar to those given by the Indian Leprosy Commission for India,[12] namely:—

Maculo-anæsthetic.	Nodular.	Mixed.
56·6	12·2	31

and they approximate to the percentage given by Hollis[13] for 188 cases in British Guiana, viz.:—

Maculo-anæsthetic.	Nodular.	Mixed.
54·80	18·08	27·12

They differ markedly, however, from Hansen's figures for Norway, which work out at practically—

Maculo-anæsthetic.	Nodular and mixed.
32	68

No explanation is vouchsafed for this difference. In Norway itself Hansen notes that dry inland regions show a greater number of maculo-anæsthetic cases than do most sea-coast districts.[14] The United Provinces of India is a very dry inland country.

The great majority of the cases in the jail were mild and visitors to the leper block were invariably surprised at the appearance of well-being of the lepers. Of these admitted after April 25th, 1905, only five were recorded as "bad cases," and a frequently recurring note in the records was, "Seems a man in good health but for maculæ." Hansen gives it as his opinion that "the natural termination of every case of nodular leprosy is to pass into the anæsthetic form if only, as occasionally happens, the patient live long enough."[15] The period during which the leper prisoners remained under observation was for the purpose of noting the development of such a chronic disease as leprosy very short, but with that proviso it falls to be recorded that while no case of nodular leprosy was noted to have passed into the maculo-anæsthetic form two cases were observed which, maculo-anæsthetic when first seen, developed nodules during the period they remained under observation. The records of the leper jail show frequent examples of this, but no instance of the opposite change. Further evidence of this development of maculo-anæsthetic into nodular or mixed leprosy seems to be presented by the not uncommon condition found in mixed cases—nodular infiltration slight and described by the sufferers as recent, together with contractures and deformities of limbs manifesting a maculo-anæsthetic infection of long standing.

In no case could a history of prodromal symptoms be elicited. However, to get from a native of India a history of the onset of the most acute disease is often a matter of the greatest difficulty, and little stress, therefore, can be put on the absence of prodromal symptoms in the history of a chronic disease like leprosy. The usual type of maculæ in those cases which presented this symptom was a patch of pale skin, not raised, more or less irregular in outline, and as a rule with a distinct margin passing directly without inflamed or hyper-pigmented border into normal skin. Out of 83 cases admitted about whom detailed notes were made 38 presented maculæ of this sort. In a few cases (five) the maculæ were of this pale kind but with a slightly reddened or inflamed margin, though there was no complaint of pain; and in a few others (four) the pale maculæ had a hyper-pigmented border. Two had a slightly raised scaly margin. Hyper-pigmented maculæ were noted in 11 cases; in seven of these the ordinary pale maculæ were also present. One of the 11 had a hyper-pigmented patch with a pale border. The size of the maculæ varied from that of a pea to tracts many square inches in extent; and the number from one or two patches to an affection so abundant that more skin was unhealthy than healthy. A few cases were seen where the skin might have been described as mottled. The parts of the body most affected were the back, chest, abdomen, buttocks, thighs, and upper arms. In one case the sole of one foot was distinctly affected. The distribution was frequently roughly symmetrical. It did not correspond at all with nerve distribution. In only two maculo-anæsthetic lepers was erythema noted, affecting in one the palm of one hand and in the other the abdominal wall and palms. Erythema was more often seen in nodular or mixed cases (one nodular and seven mixed) and generally marked a fairly acute infection. A thin glossy atrophic condition of the skin, generally of the extremities or back, was observed in 20 of the cases admitted, six of whom were maculo-anæsthetic, 12 mixed, and two nodular. A dry scaly condition of the skin was less often noted—in 11 cases, all maculo-anæsthetic or mixed. Atrophy of muscles (of the palms most frequently and next of the soles and then of the limbs generally) was one of the most common features of the disease (40 cases admitted), and almost as frequent were deformities of limbs from mutilation or contracture (34 admitted). Disturbance of perspiration was noted unequivocably only in one case. The man had distinct, well-defined, pale maculæ all over his chest, and these at the time of examination (during the rainy season) were absolutely dry, markedly contrasting with the healthy skin which was beaded with persiration.

The distribution of the anæsthesia found in the Rai Bareli lepers was not what was expected from a study of text-books. In a few cases some of the maculæ were anæsthetic, but maculæ which were anæsthetic or hyperæsthetic were the exception and the maculo-anæsthetic lepers examined conformed, with few exceptions, to one type, in which anæsthesia had no relation to the maculæ, seldom occurred in patches, and was, as a rule, confined to the distal parts of the extremities. Special attention was paid to the sensory condition of the maculæ. It has been said above that the usual type of macula was the pale patch of skin. At first it was thought that these pale patches were old maculæ and that earlier in their history they had been red or pigmented or scaly. No confirmation of this, however, could be obtained from the patients themselves; once or twice pale maculæ were noted to have increased in size during the prisoner's residence in jail, showing that some at least were recent; and finally when the distribution of anæsthesia came to be considered it was clear that the maculæ of the Indian leper differed from maculæ as described by Hansen, according to whom "pigmentation of the periphery and pallor of the centre indicate that the patch is already old and the pallid centre is always anæsthetic."[16]

The common opinion is that the anæsthesia of the maculæ, when it occurs, is due to the local action of the bacilli or their toxins on the nerve terminations or fibrils, while that of the distal parts of the extremities is due to changes in the nerve trunks. Looking at the charts depicting the areas of anæsthesia one finds it difficult to understand this: were the nerve trunks the seat of the mischief in this latter case, one would expect the anæsthesia to be more irregularly outlined, to extend up the limb to different extents in the areas supplied by different sensory nerves and not to terminate in the regular way it does often in an almost circular line round the limb. The distribution of the anæsthesia of the limbs seen in the Rai Bareli cases is more easily understood on the supposition that the nerve terminations or terminal fibrils in the limbs as in the maculæ are the parts of the nervous system affected.[17]

The symptoms peculiar to nodular leprosy varied little from those given in the text-books. It is worthy of note, however, that in addition to the sites usually affected as described therein nodules were found in two cases on the glans penis, once on the palm, and once on the sole. All these were confirmed by the presence of abundant bacilli lepræ in smears from and in sections of the nodules made after their excision. In two cases unequivocal massive lepromata were found—i.e., infiltration in plaques instead of in discrete nodules. The parts affected were in one case the hips, lower limbs, and scrotum; in the other one upper arm and the back of both elbows. The nose, eyes, and mouth were examined in a routine way in all lepers. In the nose ulcers were found in 18 cases, only one of which was a maculo-anæsthetic leper. Smears from these ulcers showed leprosy bacilli in 11 cases, one of which was the maculo-anæsthetic. In the mouth in three cases nodules were found on the hard palate and in one case on the soft palate. Two prisoners were found with ulcers of the palate of leprous origin. In only one leper was the disease found affecting the eye. A nodule formed in the lower quadrant of one cornea, penetrated to the iris, and set up iritis. The prisoner was released at this stage. Five prisoners were noted to have affections of the larynx. Only one example occurred in the jail of nodules

THE OPERATIVE SURGERY OF LABYRINTHITIS.[1]

By C. ERNEST WEST, F.R.C.S. ENG.,
ASSISTANT AURAL SURGEON, ST. BARTHOLOMEW'S HOSPITAL;
AND
SYDNEY SCOTT, M.S. LOND., F.R.C.S. ENG.,
CHIEF ASSISTANT, AURAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL, AND AURAL SURGEON, EVELINA HOSPITAL FOR SICK CHILDREN.

THE beginning of deliberate and planned operations on the auditory labyrinth for the relief of infective processes within it may be traced to the publication by Jansen of his classical cases at the Moscow Medical Congress in 1897. In 1902 much addition to our knowledge of the subject was made by Hinsberg, and following this Dr. W. Milligan and Mr. A. L. Whitehead drew attention to the subject in this country. Since this date the literature has been enriched by numerous authors and many isolated cases of the surgical treatment of labyrinthine disease have been published. We have ourselves been keenly interested in the subject for the past four years and have at various times separately published accounts of individual cases. Feeling that of late a recognition of the importance of the subject was increasing we have embodied in this paper our personal experience of 30 cases and a result of a study of it.

Surgical anatomy of the labyrinth.—An accurate knowledge of the structure and relations of the labyrinth is essential to its successful surgery. Upon such knowledge depend the recognition of the morbid processes which affect it and the ability to interpret the clinical phenomena peculiar to its diseases. Moreover, by anatomical structure and relationship the occurrence of fatal complications associated with labyrinthitis can be explained. In this summary we shall merely describe some of the main anatomical features of the labyrinth and would refer those especially interested to the more detailed description of the surgical anatomy of the labyrinth in our original paper.[2] It is convenient surgically to regard the human labyrinth as consisting of two main parts, each fulfilling through the membranous structures it contains the functions of a special sense organ —the cochlea, the essential organ of hearing, the vestibule, and the semicircular canals which contain the end-organs of static sensation. The labyrinth as a whole lies within the petrous portion of the temporal bone and is thus situated on the inner side of the middle ear, with the temporo-sphenoidal lobe of the cerebrum and the meninges of the middle cranial fossa immediately above and the cerebellum, with the meninges of the posterior cranial fossa, immediately behind. The internal carotid artery lies directly in front of, and below, the cochlea. The bulb of the internal jugular vein lies directly below the vestibule and the posterior semicircular canal. On the inner side of the labyrinth lies the fundus of the internal auditory meatus, containing the seventh and eighth cranial nerves, with their meningeal prolongations. The seventh or facial nerve also crosses the labyrinth, lying first above and then to its outer side.

The vestibule is an ovoidal chamber communicating with the cochlea in front and with the semicircular canals which lie behind. The measurements of the vestibule are: antero-posteriorly about 6 millimetres, vertically 4 to 5 millimetres, and transversely 3 millimetres. In its roof, posterior wall, and floor are the openings for the semicircular canals, while externally and in front the vestibule leads downwards and forwards into the first turn of the cochlea. The outer wall of the vestibule corresponds with the following portions of the inner wall of the middle ear, in order from above downwards: the tympanic part of the aqueduct of Fallopius containing the facial nerve, the pelvis ovalis lodging the stapes, and the upper part of the fossula rotunda. This fossula is sharply separated from the pelvis ovalis by a stout ridge of bone prolonged backwards from the promontory. Behind the fossula rotunda is a recess, the sinus tympanicus, passing upwards and backwards to the inner side of the Fallopian aqueduct. This sinus is often separated by quite thin bone from the floor of the vestibule and from the ampulla of the posterior semicircular canal, a point of clinical importance. The inner wall of the vestibule is separated anteriorly from the fundus of the internal auditory meatus and from the arachnoid sheath of the seventh and eighth nerves by excessively thin bone pierced by numerous nerve filaments. The importance of this intimate relation of the vestibule to the intracranial cavity and to the meninges of the posterior cranial fossa and base of the brain we cannot too strongly emphasise. The cochlea consists of a spirally coiled canal which takes the form of a depressed cone. The first half-turn of the cochlea leads from the vestibule and forms the promontory on the inner wall of the tympanum. The body of the cochlea lies further forwards and inwards, above the internal carotid artery, and based upon the fundus of the internal auditory meatus. The three semicircular canals open into the vestibule. They lie in planes which are at right angles to each other, the external canal being approximately horizontal, while the superior and posterior canals are approximately vertical. We have satisfied ourselves that the planes of the semicircular canals on opposite sides of the head in no instance exactly coincide. The proximity of the ampullæ of the three canals to the middle ear is important, the superior and external ampullæ lying close to the inner wall of the attic and aditus, while that of the posterior canal is close to the sinus tympanicus.

Guides to the vestibule.—One of the most important guides to the vestibule is the outer crus of the external semicircular canal, a part which is liable to invasion by disease. This canal forms a conspicuous eminence on the inner wall of the aditus and antrum; it should invariably be carefully inspected. Its ampulla lies in front of the eminence and immediately above the facial nerve. On following an opening in the external canal forwards and slightly upwards the ampulla is easily found, close to its opening into the vestibule. A second guide to the vestibule is the pelvis ovalis below the Fallopian aqueduct. This is generally only imperfectly visible from the mastoid aspect during the radical operation on the middle ear, but can be seen when looked for along the external auditory meatus.

The course of the facial nerve in relation to the labyrinth and middle-ear.—The facial nerve leaves the fundus of the internal auditory meatus through its upper and anterior quadrant; its subsequent course may be divided into three parts. The first passes outwards and slightly forwards and measures one-eighth of an inch. It terminates in a chamber lodging the geniculate ganglion. The second part passes from this ganglion backwards and downwards at right angles to the first. Its course is straight and is inclined about 15° to the horizontal: it measures nearly half an inch. Of this the middle quarter inch of the aqueduct is visible in the tympanum, exposed on its outer and lower surfaces. The lower wall of this part of the canal is often incomplete. Below it is the pelvis ovalis. Above are situated the ampullæ of the external and superior semicircular canals; to its inner side is the vestibule. The last eighth of an inch of the second part of the facial nerve is buried in the posterior tympanic wall and lies above and behind the flask-shaped chamber of the stapedius muscle. The third part of the nerve is about half an inch long and passes downwards and a little outwards and backwards at an angle of 120° with the second part, emerging at the base of the skull, through the stylo-mastoid foramen. The third part of the nerve is in relation with the deepest part of the posterior meatal wall.

Morbid anatomy and pathology.—The inflammatory processes within the labyrinth of which we have had experience originated in all cases within the middle ear. The entrance of infection was nearly always by definite tracts which could be recognised during operation, in other words, by perforation of some part of the outer labyrinthine wall. The most frequent and important site of perforation was the external semicircular canal as it lies in the inner wall of the aditus. Here entrance took place 14 times out of a total of 30 cases. Various parts of the inner tympanic wall were perforated less frequently, a defect of the footplate of the stapes being found in six cases, of the promontory in five, while in one perforation took place into the vestibule through the fossula rotunda. In three cases of undoubted labyrinthitis we were unable to discover the point of entrance. In almost all of our cases the antecedent otitis media has been chronic at the period of observation and there is no doubt that chronic suppurations bring about the majority of infections of the labyrinth. It is possible, however, that in some cases invasion of the labyrinth may have taken place during the acute stage of the otitis antecedent to the period of observation. Cholesteatoma was associated with perforations of growth hereby has yet to be determined. In a skiagram taken by Dr. D. Arthur but not published of Dr. Seymour Taylor's case[4] the space intervening between the heart and pericardium in the advance and retreat of the heart's action is clearly seen.

[1] Based upon a paper read before the Otological Section of the Royal Society of Medicine on March 7th, 1908.

[2] The original paper is published in full, accompanied by a bibliography, in the April number of the Proceedings of the Royal Society of Medicine, with illustrations.

The normal amount of pericardial serum is that of lubrication. The pathological stretch of capacity of the pericardium, according to G. A. Gibson,[5] has reached eight pints of serum (cardiac). According to Jackson Clarke,[6] sufficient pus has been found in this viscus to mask the whole anterior pulmonary area of resonance, yet 18 ounces of blood sufficed in my case to render the pericardium taut. Such is the elasticity and capacity of the pericardium.

In spite of Dr. Taylor's strictures, my treatment of aneurysm medically would be rest (relaxed periodically), limited fluid, as much iodide of potassium and lactate of calcium as the patient could bear, and a prolonged stay at Woodhall, Sandrock, or Malvern—calm retreats whose spa waters are more or less rich in iodine, bromine, alum, and iron.

West Acton, W.

THE PRECIPITIN REACTION IN HYDATID DISEASE.

By D. A. WELSH, M.A., B.Sc., M.D. Edin.,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF SYDNEY, NEW SOUTH WALES;

AND

H. G. CHAPMAN, M.D., B.S. Melb.,
DEMONSTRATOR IN PHYSIOLOGY IN THE UNIVERSITY OF SYDNEY, NEW SOUTH WALES.

IN July, 1907, Fleig and Lisbonne[1] announced that they had succeeded in demonstrating the existence of a specific precipitin in the blood serum of an individual affected with a hydatid cyst and in the serum of animals immunised with hydatid products. They also emphasised the diagnostic significance of the reaction. Previous work[2] by Ghedini, by Joest, and by Gherardini had yielded contradictory results. With the more abundant material at our disposal we have been able to corroborate and to supplement the main observations of Fleig and Lisbonne in regard to hydatid invasions in the human subject. We have found that when a sufficiency of blood serum is mixed with a suitable hydatid fluid and the mixture allowed to stand for 18–20 hours at the room temperature, a well-marked precipitate never fails to appear if the serum be taken from a patient infected with hydatids (nine cases), and that precipitation does not occur when the serum is taken from persons not so infected (four suspected cases and five healthy controls). In the four suspected cases examined by us a negative reaction was obtained, and at operation in each case the absence of hydatid invasion was revealed. These results are so consistent, though as yet few in number, that they encourage us in the belief that in the precipitin test for hydatid invasion we have a reliable means of diagnosis. We find, however, that certain conditions are essential to the satisfactory performance of the test.

In regard to the serum (antiserum) developed in a hydatid patient, our experience has been that, with few exceptions, it is characterised by a low precipitable content. Hence, as noted by Fleig and Lisbonne, about 12 drops of the patient's serum are usually required to yield a satisfactory amount of deposit. In a previous paper[3] dealing with precipitin antisera prepared in the rabbit by injections of alien blood serum or of egg-white, we noted that two drops (0·1 cubic centimetre) of the antiserum were usually sufficient to yield a well-marked precipitate. We were also led to the conclusions that the precipitate was derived mainly from the antiserum and that different antisera might differ greatly in their precipitable content.

Fleig and Lisbonne observed that the anti-substances in the serum of a hydatid patient may gradually disappear after operation. That this disappearance of the precipitin is not necessarily associated with removal of all the cysts is shown by one of our cases. In a man, aged 42 years, with multiple hydatid cysts of the liver (not all of which could be removed at operation) we found a well-marked reaction before operation, but at the end of the sixth week and again at the end of the seventh week after operation the serum yielded only a minute trace of deposit. The patient died in the eighth week after operation, having become rapidly weaker and more emaciated, and it may be that in these circumstances his capacity for reaction was failing. On the other hand, a girl, 14 years old, with multiple hydatids of the peritoneum following a ruptured hydatid of the liver gave a well-marked reaction eight weeks after operation. She was well nourished and was leaving the hospital apparently cured. The indication, however, was that she was still infected with hydatids and that the tissues were reacting to their presence.

In regard to the hydatid fluid, our practice has been to pass it through a Chamberland filter. We have obtained more abundant precipitates with one cubic centimetre hydatid fluid than with two cubic centimetres (as recommended by Fleig and Lisbonne), probably because the small amount of the homologous protein contained in the hydatid fluid is sufficient to produce a marked precipitation in the antiserum, while the interaction is not hampered by over-much dilution. This also is in harmony with our previous work on serum and egg-white precipitins.

In the course of our experiments with hydatid precipitins we encountered one hydatid fluid which gave no precipitate, in addiments of two cubic centimetres, either with the serum of the patient from whom it was obtained, or with the serum of other hydatid patients. When, however, these tubes, after standing 48 hours without showing any precipitate, each received the further addition of one cubic centimetre of clear fluid from another hydatid invasion, distinct precipitates were obtained. It was certainly anomalous to find that the first hydatid fluid failed to precipitate the serum of the patient from whom it was obtained, while the serum of that patient reacted strongly with the hydatid fluid obtained from a different patient. We may note that each of the hydatid fluids above referred to contained, approximately, the same amount of albumin (about 0·025 per cent.).

The fact that not all hydatid cysts contain fluid capable of interacting to give a precipitate with the serum of the patient may be an explanation of the negative results obtained by earlier workers. What we would emphasise is that hydatid fluids may vary greatly in their capacity for interaction with the serum of a hydatid patient, but that a hydatid fluid which reacts strongly with the serum of the patient from whom it was obtained reacts also strongly with the serum of other hydatid patients. These facts are of importance in the selection of a stock of hydatid fluid in the diagnostic applications of the test.

Summary of cases of hydatid invasion, all of which gave a marked precipitate reaction when tested before operation.—1. Male, 35 years. Three small hydatid cysts with clear contents in peritoneum. Hydatid of liver removed eight years ago. 2. Male, 42 years. Multiple hydatid cysts of liver, some of which were full of clear fluid, others shrunken and inspissated. Not all cysts removed, yet reaction very feeble six and seven weeks after operation. Death in eighth week. 3. Male, eight years. Large single cyst of liver with clear contents. 4. Female, 14 years. Multiple hydatids of peritoneum with clear contents, following ruptured hydatid of liver. Marked reaction eight weeks after operation. 5. Male, 13 years. Single hydatid cyst of liver with clear fluid contents. 6. Female, 17 years. Multiple cysts of peritoneum with clear fluid contents, dense matted adhesions. 7. Male, 50 years. Suppurating hydatid cyst in muscles of thigh, well-marked reaction three weeks after operation. 8. Male, 48 years. Large hydatid cyst of liver with slightly turbid contents. 9. Male, 23 years. Large hydatid cyst of liver with slightly turbid contents.

Conclusions.—1. The interaction between selected hydatid fluids and a sufficiency of the serum of a patient affected with hydatid disease has, in our experience of nine cases, never failed to give a positive precipitin reaction when tested before operation. 2. Not all hydatid fluids are capable of eliciting this reaction, and their failure is not associated with any noticeable diminution of their protein content. 3. Persistence of a marked reaction some weeks after operation probably indicates the continued presence of the parasite, but the disappearance of the reaction does not necessarily indicate complete removal of the cysts. 4. A positive reaction is independent of the site of the hydatid cyst (hepatic, peritoneal, muscular) and independent also of the nature of its contents (clear, turbid, or purulent).

the external semicircular canal and the inner tympanic wall, directing particular attention to the pelvis ovalis and to the fossula rotunda. It is scarcely necessary to state that, for the conduct of such examinations, the cavity must be well illuminated and free from blood. In deliberate operations on the labyrinth the preliminary radical mastoid operation is performed and it is essential that as much room as possible should be made available by the free removal of the boundaries of the mastoid operation cavity and of the posterior meatal wall. It has been found necessary in some cases also to remove the anterior wall and floor of the bony external meatus. We shall describe the operations which we have carried out for labyrinthitis, quoting certain cases in illustration and referring to the others under the numerical headings of the original paper. The order of cases is categorical not chronological.

Superior vestibulotomy.—To open the vestibule from above the outer limb of the external semicircular canal is followed forwards above the facial aqueduct until the ampulla is opened. When this is effected the vestibular roof is completely removed by extending the operation forwards and upwards into the ampulla of the superior semicircular canal and the lower part of its ascending limb and destroying the small mass of compact bone which lies between the proximal parts of the two canals. Though a simple and short procedure we have found this an inadequate operation to ensure drainage of the vestibule if carried no further. After removing the roof of the vestibule the external and superior ampullary nerves can be easily destroyed with a small sharp curette as they run in the anterior and outer wall of the vestibule at the level of the upper margin of the facial aqueduct. We have discarded simple superior vestibulotomy after performing it twice only (Cases 1 and 2) and losing one patient through the inefficient drainage afforded by the simple superior opening. We consider such cases require double vestibulotomy (*vide infra*).

CASE 1.—The patient was a male, aged 12 years. Cholesteatoma; erosion of external canal and roof of the vestibule (left side). Symptoms: none referable to labyrinth; recent acute mastoiditis. Operation: radical. Fistula of external canal leading into vestibule; the vestibule was curetted but not opened below. There was no escape of cerebro-spinal fluid. Result: meningitis developing on the third day; death occurred on the fourteenth day.

The second case in which we performed this operation was complicated by cerebellar abscess to which death was due. Hinsberg described one fatal case similar to Case 1.

Superior vestibulotomy with complete removal of the canals.—We have performed this operation once only, in a case of post-suppurative vertigo (Case 3). It is a tedious undertaking and we now know that the symptoms can be relieved by an operation on the vestibule without removal of the canals.

Inferior vestibulotomy.—To perform this operation the vestibule is opened below the facial nerve by removal of its outer wall. This opening, which should be as complete as possible, is attained by removing the stapes if still present and cutting away the ridge of bone between the fenestra ovalis and the fossula rotunda. In this way the outer wall and part of the floor of the vestibule are removed, while it is not anatomically necessary to interfere with the fenestra rotunda, or to remove the membrana secundaria. The posterior ampullary nerve may be destroyed by introducing a small curved curette and cutting against the inner and posterior part of the floor of the vestibule. Case 4 of our series was an example of *simple inferior* vestibulotomy performed for tuberculous invasion of the vestibule through the inner tympanic wall.

Inferior vestibulotomy with partial or complete removal of the cochlea.—When the first half-turn of the cochlea is diseased it is easily opened by working forwards from the vestibule. The second turn of the cochlea lies deeper and higher and is difficult of access, except in infants, unless the bony meatus is removed. This should be done as far as the annulus tympanicus anteriorly and below, the periosteum of the tympanic plate being pushed forwards and held aside with a narrow flat retractor. In following up disease in the cochlea the position of the internal carotid-artery must be borne in mind lying below, in front, and somewhat internally. Inferior vestibulotomy was performed in five cases of our series (Cases 4, 5, 6, 7, and 8).

CASE 8.—The patient was a female, aged 13 years, who was admitted with chronic suppurative otitis media on the left side. Symptoms: headache, vomiting, and convulsions followed by unconsciousness. A radical mastoid operation was performed. Cholesteatoma was found in the antrum and tympanum; the promontory had been destroyed by disease. The vestibule was opened below the facial nerve and the first half turn of the cochlea was removed. Result: complete recovery.

We have come to regard inferior vestibulotomy as a good and adequate means of draining the vestibule in cases of infection. The removal of the first half turn of the cochlea is especially indicated when there is complete perosseous deafness on the affected side and when the promontory is the seat of disease.

Double vestibulotomy.—These two operations, superior and inferior vestibulotomy, may according to the indications be combined in various ways along with their extensions. Of these combinations the most important is that of superior with inferior vestibulotomy, constituting what we have called "double vestibulotomy." While our methods differ in some particulars, the operation is, we find, essentially that described by Dr. Milligan under the title of the "bridge operation." Cases 9, 10, 11, and 12 of our series were examples of double vestibulotomy.

CASE 9.—The patient was a male, aged 33 years. Though deaf in the left ear he had noticed no discharge whatever. There had been constant vertigo with paroxysms, accompanied by vomiting; he had several times fallen down as if in a fit. Objects appeared to move from left to right. The patient felt as if he were moving from right to left. In walking or standing with eyes closed he swayed to the left. Tuning fork on the vertex referred to the right ear. He had severe headache and pain in the ear. Otoscopic examination showed a large perforation with a dry cholesteatoma occupying the tympanum, on removal of which a small mass of granulations was seen in the pelvis ovalis. Operation: radical. There was no erosion of the external semicircular canal or the promontory. A fine probe entered the vestibule by its own weight, through the granulations in the fenestra ovalis, without encountering the slightest resistance. Double vestibulotomy was performed. Result: immediate disappearance of all symptoms. In this case facial paralysis gradually developed but afterwards completely recovered.

Cases 13, 14, and 15 were examples of double vestibulotomy combined with partial removal of the cochlea.

CASE 13.—The patient was a male, aged 38 years. There had been chronic suppurative otitis media (left), cholesteatoma, fistula of the external canal, and acute suppurative labyrinthitis. Symptoms ten weeks before operation: initial giddiness and repeated vomiting; horizontal vertigo, objects moving from left to right; had walked "as if drunk." At the time of operation he was only giddy on moving his head. He had an incoördinate swaying gait. There was no perception of sound on the left side. No nystagmus was present. The temperature and pulse were normal. Operation: radical. The external canal was opened and a defect of the roof of the vestibule was discovered. Pus was found in the vestibule. Double vestibulotomy was performed with partial removal of the cochlea. Result: loss of all vertigo and of feeling of insecurity; complete recovery. There was temporary facial paresis which rapidly recovered.

Extirpation of the labyrinth.—We reserve this term for the complete opening up of every portion of the bony chambers, i.e., double vestibulotomy with destruction of the whole length of each canal and of the cochlea. We have three cases of this description (Cases 16, 17, and 18). We think that this operation is rarely called for except in some cases of tuberculous disease—e.g., the following:—

CASE 16.—The patient was a female, aged 11 years. There was tuberculosis of the middle ear and petrous (left side); also fistula of external canal, chronic tuberculous labyrinthitis, and acute infective labyrinthitis. Operation: radical, with complete extirpation of the labyrinth. Result: rapid and complete healing.

Simple curettage of the carious portion of the labyrinthine capsule was carried out in six cases (Cases 19, 20, 21, 22, 23, and 24). None of these has been submitted subsequently to further operation on the labyrinth. In all the lumen of the external semicircular canal was found to be laid open by destructive disease, but was sealed by granulations. Labyrinthine symptoms were absent at the time of operation. A fistula in this situation may betoken a sequestration cavity, as will be seen from the following account.

Sequestrotomy.—The removal of sequestra of the labyrinth constituted the earliest recorded operations on the labyrinth. In nearly all cases in the literature the facial nerve had been the labyrinthine capsule in ten cases, accounting for seven out of 14 of the cases of fistula of the external semicircular canal, and twice leading to destruction of the footplate of the stapes. Twice the labyrinth was involved through definite regions in the spread of tuberculous disease.

Opportunities for the examination of the infective organisms of labyrinthitis have occurred in only a few cases. One of us cultivated streptococci from the vestibule in a case of acute suppurative labyrinthitis and in another we obtained a similar organism from the fluid in the internal auditory meatus post mortem. It is probable that in this, as in the other major complications of suppurative otitis media, the streptococcus pyogenes is the most frequent and important agent. The labyrinthitis set up may vary widely in intensity and extent; it may be of an acute suppurative type or may be chronic and progressive, leading to the formation of granulation tissue within the labyrinth. Acute suppurative labyrinthitis is probably always diffuse, but chronic granulating labyrinthitis may have any extent from that of a local invasion in a semicircular canal to the involvement of every part of the chambers. In the early stages of acute labyrinthitis the membranous structures are intensely injected, the membranous canal instead of being invisible appearing as a brilliant red thread when the bony canal is opened. The perilymph in the vestibule is turbid and blood-stained and the utricle and saccule cannot be recognised. Blood-stained and turbid fluid also occupies the scalæ of the cochlea. In histological sections of the cochlea in a case of fatal acute streptococcal labyrinthitis one of us found infiltration and proliferation of round cells completely obscuring the finer features of the membranous cochlea.

We have been unable to find any traces of the normal structures in the granulation tissue from the vestibule in cases of chronic labyrinthitis. The osseous labyrinth is also involved in labyrinthitis, to a greater or less extent, showing local caries or necrosis according to the acuteness of the inflammation of the dense labyrinthine capsule. Such necrosis may include virtually the whole of the labyrinth, but it seems the rule for the cochlea on the one hand and the vestibule and canals on the other to form separate sequestra rather than to be exfoliated in continuity. Vestibular sequestra generally include some part of the wall of the internal auditory meatus. Where the inflammation has been less severe or has been arrested by drainage the labyrinthine cavities may become occupied after resolution by a fibrous tissue mass which may subsequently ossify. The cochlea appears frequently to escape either wholly or in its apical portion when the vestibule is the site of a granulating inflammation. These various conditions were observed during operation, acute diffuse labyrinthitis being recognised five times, in three of which pus escaped when the vestibule was opened, while granulation tissue was removed from the vestibule in four cases of chronic labyrinthitis. We saw three cases of local granulations within the external canal in which no labyrinthine symptoms were present, and the vestibule was not explored. There were six cases of sequestration, two involving both cochlea and vestibule with canals, two of the cochlea only, and two of the vestibule and canals only.

The inflammatory process shows a marked tendency to spread from the labyrinth along the perineural arachnoid sheaths of the nerves in the internal auditory meatus. The effusion here may be plastic, sero-purulent, or serous. In the latter case the sheath is distended and may lead to a local area of marked distension of the subarachnoid space, between the lateral aspects of the pons and cerebellum, limited by delicate marginal adhesions; or there may be associated a general serous meningitis. In some cases infection seems to take hold upon the cerebellum with the production of an abscess, sometimes interlamellar, while clearing up within the internal meatus. The fatalities from labyrinthitis are due to this intracranial spread of infection, except in such rare cases as one of our series which succumbed to acute streptococcal septicæmia. Two cases of our series died from cerebellar abscess, one without operation; one from consecutive meningitis after an inadequate operation on the labyrinth, and one from acute internal hydrocephalus without operation on the labyrinth. The last form of fatal issue appears to be directly consequent on the localised serous meningitis described above. We have not met with abscess of the saccus endolymphaticus nor with isolated erosion of the superior canal, conditions which have been recorded by other observers; the anatomical grounds for such conditions are sufficiently obvious.

Symptoms and special tests.—It is a remarkable thing that many cases of gross labyrinthine disease present no obvious symptoms of the condition. Of our patients, nine had no symptomatic features calling attention to the labyrinth, among them being four cases of fistula of the external canal and two of sequestration of large portions of the labyrinth, while in another tuberculous disease had invaded the vestibule. Where symptoms are present the most frequent and characteristic is vertigo and of the 26 patients operated upon no less than 16 were giddy. We have reserved the term vertigo for a sense of rotation in a definite direction, either of external objects or of the patient. The plane of apparent rotation is most commonly horizontal, 11 of the 16 being of this class. More rarely a vertical or oblique plane is met with. In four cases there was a marked tendency to fall towards the affected side. Vertigo may be short lived and may disappear permanently after a few days, or may persist for many months, either constant with exacerbations, or intermittent. It is interesting physiologically that an isolated lesion of the cochlea was never associated with vertigo. Vomiting may be due to labyrinthine disease or to some concomitant intracranial lesion. Its association with vertigo produces a clinical picture which in combination with middle-ear suppuration is almost certainly diagnostic of labyrinthitis. 14 of our cases vomited at some period of the disease, but in five of them intracranial complications may have been productive of this symptom. Cochlear symptoms are, on the whole, less strongly marked: tinnitus was only complained of by three patients, though all were markedly deaf. Local deep-seated pain has been prominent in acute labyrinthitis. Headache is common, but a severe type is not. Constant and severe headache may be caused by the presence of a sequestrum. General disturbance with raised temperature and frequent pulse has only occurred in acute labyrinthitis. In spite of the frequency of vertigo we have not met with spontaneous nystagmus.[3]

While there may be a complete absence of symptoms under ordinary conditions it is probable that all cases of labyrinthine disease may be made to show symptoms in special circumstances and we have found the following special tests of such value in eliciting them that we have made them a part of our routine investigation. 1. Rombergism. The patient shows abnormal instability and this may be especially marked on one side when the attempt is made to stand on a single foot with the eyes closed. As a rule, swaying or falling is toward the affected side. 2. Gait is often rather characteristic, even with the eyes open, in cases of vertigo. The feet are planted unnaturally widely and in walking along a straight line there is a tendency to deviate to the affected side, which may be visibly corrected by voluntary readjustments. There may be marked ataxic gait. 3. Nystagmus may always normally be evoked by rotation and possesses a quite definite type in the normal subject. We have found abnormalities or absence of nystagmus after rotation in cases of known labyrinthine lesion and consider that such reactions are strong evidence of the presence of some disturbed condition of the labyrinth.

Operative interference is called for in all cases where there is good evidence of infective disease, resting either on the presence of symptoms and the response to special tests or on operative discovery in the course of the radical mastoid operation. As the cases without symptoms share all the risks of the condition a most careful search should always be made over the whole of the area of the outer labyrinthine wall. We consider that all cases in which the vestibule or the ampullary ends of the canals are involved should, for the safety of the patient, be thoroughly opened up and drained. Cases of fistula or caries of the canal behind the ampulla presenting no special symptoms should be locally curetted and given their chance of healing. It is well to remember that a fistula of a canal may lead into the cavity which incloses a deep-seated sequestrum. When the promontory is perforated the area of disease should be completely removed and the vestibule should at the same time be opened and drained.

Operative surgery with illustrative cases.—The main conditions which call for surgical aid in the form of deliberate operation on the labyrinth appear to us to be the incapacity produced by vertigo and the danger of infective meningitis. In operations on the middle ear for the relief of chronic suppurative otitis media we invariably note the condition of the outer wall of the labyrinth—that is, of the eminence of said, is forced to overwork itself. The wards often contain 40 or 50 beds. Night duty is relegated to perfect beginners, without experience and without ability, quite unaccustomed to hospital discipline. The natural result of these bad sanitary conditions in the hospitals of Paris is that the mortality from consumption is something appalling. The staff has only a very hazy idea as to its moral responsibilities. Tips are allowed as quite a matter of course. Be it said, however, that these women are at heart extremely good-natured. The evil lies in their social position. Tips do not humiliate them. Permission to marry is disastrous. The result is additional fatigue and overwork, for these women must use up their leisure moments in looking after their homes.

---

[3] Since this was written we have met with spontaneous nystagmus in a case of acute labyrinthitis.

A serious omission in the organisation of the hospital staff is the absence of a woman at the head of affairs—the matron of the English hospitals. The result is that the promotion of a nurse is more often due to political influence than to personal merit. This, no doubt, is a matter of astonishment to the English, but as the municipal authorities are at the head of affairs in the French hospitals their great object is to stand well with their electors rather than to consider the rights of the nursing staff. To rightly judge it is above all expedient to take into consideration the ways of the country; thus, what would cause astonishment in England comes as a matter of course in France. This will account for the fact that in all the wards of the French hospitals men nurses work side by side with the women nurses. Do not let us overlook the fact that in the French hospitals men—nurses and employees of all sorts—are very numerous. Thus often the women nurses are married and are lodged with their husbands in the hospital.

These are the things which render it so difficult rightly and properly to recruit the hospital staff. Let us examine for a moment how this situation may best be remedied. Reform is possible, but there must be less centralisation, requiring everywhere an identical organisation. As to the Parisian hospitals one must not seek to reform them all at once. At first the reform should only be applied to *one single hospital*, for preference a new one, for it naturally follows that a staff recruited according to the new régime cannot have mixed with the existing one. The wisest thing to do would be to adopt the English system, which is the best—offer to young girls the means of acquiring a diploma which would enable them to earn their living and in return require of them their services in looking after the sick. The question of money is a secondary consideration. Above all, a moral reform is absolutely essential.

To turn out a good nurse we must take her from surroundings entirely different from the present one. We must try to get young girls who have received a certain amount of instruction and a fair education. The celibacy of the nurse must be insisted upon. This reform is absolutely imperative in spite of the prejudices existing in France on the subject. There must be a woman at the head, answering to the "matron," who shall be held responsible for the staff and shall be in direct touch with them. The nurse must undergo a practical training, given in the wards by other nurses who have themselves passed through the training that they are imparting to the beginners. The theoretical teaching of the doctors is but the complement and *not* the principal. In France, too, much importance is laid upon theoretical instruction to the exclusion of the practical. The duties of a nurse are quite different and quite separated from those of the domestic "ward maids." The number of men employed and, above all, lodged in the hospital should be greatly reduced. A certain number of male employees is, of course, necessary but only women should be called upon to nurse the sick. Sweeping changes must be made in the treatment of the nurses, both physically and morally. As in the English hospitals, they must no longer be treated as servants. They must have every consideration and, at the same time, gain an honest livelihood, both as to salary and as to food. Above all, they must have comfortable quarters, cheerful and bright, where, after their many hours of hard work, they may retire and feel at home.

Now, these reforms would not be very costly: it means changing the hospital into a training school, teaching the staff hospital and private nursing, and, in return for such teaching, having a call upon their services in nursing the sick, as is done in England. Their training once acquired, these nurses would gain their diplomas and be capable of looking after the wards and in the end become *fully qualified hospital nurses.* Quite recently the administration of the Assistance Publique tried to improve the condition of the nurses. First and foremost, they tried to increase the salary of the nurses, so that they might be able to raise themselves, put something by—in a word, accomplish a moral reform.

Many practical reforms have recently been attempted in the private hospitals of Paris with reference to the creation of a staff upon the new lines. It is to be hoped that this example may be followed by the large hospitals. These efforts should receive the encouragement of the doctors and of the public and have no sectarian interest; still less must they be anti-sectarian.

Aix-les-Bains.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

SPONTANEOUS RUPTURE OF THE HEART.

By A. F. Theobalds, M.B., Ch.B. Edin.,
PATHOLOGIST AND ASSISTANT MEDICAL OFFICER, WEST RIDING ASYLUM, WAKEFIELD.

THE following case of a patient surviving spontaneous rupture of the heart for six days is worth recording. The patient was an inmate of the West Riding Asylum for 26 years and died in November last, aged 65 years. He suffered from chronic mania, and on the whole was fairly quiet and in good health. About a year ago he was found to have a mitral systolic murmur but it did not seem to inconvenience him. One Tuesday he was seized suddenly with what was thought to be an ordinary syncopal attack and was put to bed. He soon recovered, however, but on Sunday morning died suddenly while still in bed.

At the *post-mortem* examination the pericardium was found to be distended with fluid blood; the heart was enlarged and weighed 375 grammes. On the anterior surface of the left ventricle near the middle and to the outer side was seen a small sub-epicardial hæmorrhage of about the size of a halfpenny, on the outer side of which was the external aperture of the rupture of about the size of a pin's head. On cutting through this the rupture was seen to extend from the inner surface of the ventricle and to be V-shaped. The wall of the ventricle was fully half an inch thick, but was pale, soft, and flabby. The coronary arteries, however, were apparently healthy. The mitral valve was dilated and there was slight thickening of the aortic valves, the first part of the aorta also being slightly roughened. The vessels at the base of the brain were markedly atheromatous and the choroid plexuses were calcareous.

A somewhat similar case, also in an insane patient, was published by Dr. H. Kerr in THE LANCET in 1904[1] in which he refers to the rarity of the condition. In his case, however, the patient apparently succumbed immediately, although, as in the one above, there was no history of sudden exertion or strain.

I am indebted to Mr. W. Bevan-Lewis for permission to publish this case and to Dr. J. A. Creighton, assistant medical officer, for the clinical notes.

Wakefield.

NOTE ON A CASE OF OSTEO-FIBROMA OF THE MAXILLA.

By Andrew Wylie, M.D., C.M. Glasg.,
ASSISTANT SURGEON, CENTRAL LONDON THROAT AND EAR HOSPITAL.

With a Pathological Report by V. H. Wyatt Wingrave, M.D. Durh., *Pathologist to the Hospital.*

THE patient, a man, aged 53 years, consulted me on Jan. 9th complaining of a "growth in the palate" of 25 years' duration. He suffered no pain and very little discomfort; in fact, he stated that beyond a certain amount of anxiety it gave him no trouble, and having grown slowly and gradually he had got quite used to it. Mastication and deglutition were performed without any difficulty, and with the exception of a slight "thickness" or impaired resonance destroyed by the disease or was sacrificed in extracting the sequestrum. In our experience sequestra involve either the vestibular region or the cochlea, or both. While we have met with sequestra of both parts in the same labyrinth we have not met with a case in which the whole labyrinth formed a continuous massive sequestrum. Sequestra of the cochlea readily separate, consisting generally of the promontory and first half turn only. The converse is the case with sequestra of the vestibule and canals. These are deeply situated on the inner side of the facial nerve and involve the posterior wall of the internal auditory meatus. Such sequestra lie posteriorly against the dura mater covering the cerebellum. Sequestra of the vestibule and canals must be sought for, and should be sought for, when there is reasonable ground for suspecting their presence. They may be discovered by probing fistulous tracks and may be suspected where granulations are persistently re-formed. The sequestrum must be freely exposed before attempting to dislodge it. It may be necessary to cut away apparently intact portions of the labyrinth before the dead mass of bone is exposed, for the typical sequestrum does not include any part of the outer surface of the labyrinth. Three of our cases (Cases 25, 26, and 14) were examples of sequestrotomy, the sequestra being removed in each case by the posterior route—i.e., behind the facial nerve. Case 29 was an example of spontaneous exfoliation of the cochlea.

---

[1] THE LANCET, Dec. 31st, 1904, p. 1832.

In addition to the 26 cases illustrating operative procedures on the labyrinth our knowledge of infective labyrinthitis was extended by other cases which were not operated upon. We quoted four of these cases (Cases 27, 28, 29, and 30) which appeared to present important clinical or pathological features bearing on the surgery of the labyrinth.

Results.—The cases submitted to operation on the labyrinth have healed with such absolute uniformity that we are led to suspect that the cause of some at least of the failures after the radical operation may be due to disease of the labyrinth. In every case in which vertigo was present it has been completely and permanently relieved. We have been fortunate in having no case of permanent facial paralysis. In only one case has there been a death due to the operation, this being after an inadequate operation, superior vestibulotomy. We lost two other cases through not operating on the labyrinth.

In conclusion we would assimilate the grounds for operation in labyrinthitis with those justifying the radical mastoid operation, and we believe that the time will come when no aural surgeon will be content to leave an infective cavity in such perilous proximity to the meninges.

THE NURSING DIFFICULTY IN FRANCE.

BY J. DARDEL, M.D. PARIS.

FOREIGNERS visiting the French hospitals have often heard the medical officers complain of the nursing staff. These complaints are well founded, but to what may we attribute them and how may they be remedied? In former times the French hospitals were served by nuns. In Paris, above all, many communities of *religieuses* undertook the nursing required by the Assistance Publique. It is a well-known fact that the Assistance Publique is entirely taken up with the care of the very poor, their nursing, &c., and visiting them in their own homes, for the French law makes the working of independent hospitals an affair of extreme difficulty.

Some 30 years ago the Municipal Council of Paris decided to secularise the hospitals. This was a very tedious and difficult undertaking, for it concerned no less than 15 of the larger hospitals. At the present moment an almost complete change has been effected and the towns and the provinces are also following suit in the example given by Paris. The new enactments of the French Government (1901) make it simply a question of time when, in the not very distant future, the nursing of the nuns will become simply a remembrance of the past. What object had Paris in view when she decided upon so sweeping a reform? The secularisation of the hospital staff is merely a political move.

Let us just touch upon the fundamental cause for this great reform. First and foremost it was a question of dealing a blow at a party which had been defeated in the electoral struggles. It is worthy of remark that in the discussions of this period (1880-85) questions of a technical order occupy but little space. In fact, there was small cause of complaint against the nuns. They fulfilled the rôle of sisters and staff nurses. They were few in number, about two for each ward; they did all the waiting and were held responsible by the medical officers and the administration. Under them a non-religious staff rendered valuable assistance to the sick. This assistant staff was badly recruited, badly paid, and without training. The faults which they committed were often attributed to the nuns and cleverly brought home to them. The nuns were also accused of being too conservative. This is quite possible, for these *religieuses* were far from being perfect and there was much room for improvement in their training. But we must not overlook a date which was of great importance. The secularisation of the hospitals in France coincides with the period of antiseptic treatment. The idea of antiseptic and of septic treatment was taught as something new. It was a period of transition and the medical corps, as well as the nursing staff of the hospitals, had to adapt itself to new ideas. The old nuns, like all the others, had to go through a special technical training. The religious influence exercised on the conscience of the sick was of rare occurrence. On the other hand, the nuns knew how to suppress all licence and evil tendencies in the wards; they knew how to comfort the sick, by whom they were held in great esteem, as also by the doctors and medical students. No one ever dreamt of taking any liberties with the nuns.

When in the year 1880 the secularisation of the hospitals was decided upon, a thoroughly trained staff not being available, the administration accepted the first comers, whether competent or not, who nursed the sick—without even the most elementary ideas of the work—under the supervision of the nuns. This staff, somewhat domestic, was given almost the entire control of the wards. It was soon noted that they stood much in need of instruction. Schools for the nurses and staff were founded where, in certain cases, they had to be taught how to read. Those schools have now been open for 27 years and the results may be well guessed at. The technical instruction given there has borne fruit, but young girls with a sufficient moral education have not been attracted to them. They have turned out nurses capable of good work; their education has been improved, but the social position of the nurses has not changed. Now, so long as this is so really good nurses will be at a premium. What lowers the nursing profession in France is not the poor salary which they receive but the inferior rank of the nurses themselves, combined with the arduous work required of them and the little compensating comfort. The nurses in the Paris hospitals are badly paid when they enter. The salary gradually rises and the remuneration becomes equal to that obtained by nurses in England. This salary cannot be looked upon as a fortune but it is sufficient to permit of a woman living in comparative comfort if she is not encumbered with a family.

What kind of life is led by the nurses? They are lodged in dormitories which are both dirty and dismal, often mere garrets. Air is wanting and heating is unprovided. Furniture is very scanty, a wardrobe or a chest of drawers for little personal effects being all that is supplied—less comfort than in the room of a general servant. There is not a corner where the unfortunate woman can perform her most private toilette. The water-closets—common to both sexes—are very badly kept. There is no bathroom and no recreation or rest room. The dormitories are the same for those working during the day or the night, which means that in them perfect rest is almost impossible. The food is very bad and very badly served. To ask for better is out of the question. The director is an official of high importance and he, like the others, is but a tool of the great administrative machinery. It is necessary that there should be no trouble and no complaint. Neither can he ask for supplementary credit. In short, the nurse, no matter what her class is or her degree, is treated as a servant. All may be traced back to this mistake which is fundamental—the little consideration shown to the staff of nurses. The sick, the management, the medical officers, one and all are allowed regrettable familiarities with these poor women. The directors of the hospitals have always mixed up the classes, when a very clear line of division should be drawn between them. Young servants become nurses in the course of time by means of examination or by protection. This lamentable confusion prevents young girls who have had a certain amount of education from entering the hospitals.

This staff, so badly treated physically and morally be it paths. A diagram showing lateral movements of the jaw had been obtained by the subject sitting facing the wall. A demonstration was then given of the geometrical theory of the centre of rotation for plane motions. It was shown how for any such motions of translation combined with rotation two polygons and curves called "centrodes" could be derived, these "centrodes" being uniquely associated with the particular movement. The movement could be reproduced by rolling one centrode upon the other. Charts and models were exhibited illustrating the paths of the condyle and symphysis and the centrodes derived from these paths. Mr. Bennett proved by these means that for the ordinary movements of the mandible in opening and closing the mouth there was no fixed centre of rotation, but that the centre was constantly shifting its position, and its path might be marked out starting behind and below the condyle, passing backwards and downwards, then forwards, and finally upwards and forwards, finishing at a point a little below the condyle path. The general character of this path exhibiting the successive positions of the instantaneous centre of rotation was well shown in a large wooden linkwork mechanism based on mathematical calculations. The movement of the condyle and symphysis was demonstrated and the instantaneous centre at any particular movement found at the point of intersection of two moving indicators. Other details in connexion with the correlative positions of the paths of the condyle and symphysis were referred to and several interesting observations regarding lateral movements of the jaw were made. Mr. Bennett concluded by making some remarks on the bearing of his investigations on the question of an ideal articulator and the taking of "bites" for edentulous cases.

Medico-Psychological Association.—A meeting of the Northern and Midland Division of this association was held on April 30th, Dr. P. W. Macdonald, the President of the association, being in the chair.—Dr. Guy R. East, of Northumberland County Asylum, Morpeth, read a paper on a case of Cretinism, illustrated by photographs. The patient presented all the typical symptoms of this disorder. An interesting feature was the enlargement of the thyroid gland which was chiefly confined to the right lobe. This tumour was elastic to touch, freely moveable, painless, and in no way hampered respiration. The blood revealed a reduction in the percentage of hæmoglobin and the urine showed an increase in the amount of urea excreted. The patient had been under treatment with thyroid extract but had shown no signs of mental improvement.—The President remarked upon the rarity of cretins in asylums and said that after careful inquiry he had not found a single case in Dorset.—Dr. C. F. F. McDowall, of the City Asylum, Newcastle, read a paper upon the Occurrence of General Paralysis in Father, Mother, and Son. The cases were recorded, not that individually they were remarkable, but collectively they were extremely interesting, if not unique. In the only case, that of the boy, which might have caused a moment's hesitation in diagnosis, a post-mortem examination revealed characteristic lesions of general paralysis. The duration of the mother's attack was 10 years, while she had previously been under control in an asylum. The signs of general paralysis were only seen in her case five years before death. She was then living apparently contented in an asylum and why the cerebral degeneration should have commenced appears obscure. She was exposed to no strain or stress nor did she suffer privation. Syphilis could not be definitely proved but it could not be excluded. The man was a loose liver, while the boy showed certain suggestive lesions of congenital syphilis. The son was regarded as an undoubted example of juvenile general paralysis.—In the discussion which followed the President suggested that there was not sufficient proof that syphilis was present and he did not accept the proposition "No syphilis—no general paralysis." He could name cases of general paralysis in country districts in which he was satisfied that there was no syphilitic taint. He said it was remarkable that the mother had such a long period of excitement.—Dr. J. Middlemass (Sunderland) remarked on the long history in the mother's case and the weight of the son's brain (65 ounces) was unusual. He quoted a case of a congenital imbecile developing general paralysis in Morningside Asylum.—Mr. Gilbert E. Mould (Rotherham) continued the discussion.—Mr. Harold B. Cross, senior assistant medical officer at Storthes Hall Asylum, Huddersfield, showed two interesting cases, one presenting Marked Conical Cornea, and the other Atrophy of the Right Deltoid and Weakness of the Muscles of the Arm, the cause of which could not be ascertained.—Mr. Michael W. Kelly, assistant medical officer at Storthes Hall Asylum, also showed two cases: 1. A boy, aged 14 years, with Petit Mal. During the attacks, which lasted about 20 seconds, he used bad language. He awoke at night with a shout as if dreaming, but stated that he did not dream. Sometimes he had 20 of these during the night; at other times he might go four or five weeks without a fit. 2. A female, aged 30 years, who in January, 1906, developed Acute Melancholia with Active Suicidal Tendency. In the following September and October she refused food and had to be tube-fed and appeared to be becoming demented. She was transferred to Storthes Hall on March 5th, 1908, began to take interest in her surroundings, and now appeared to be on the road to recovery.

Medico-Legal Society.—A meeting of this society was held on April 28th, Mr. Walter Schröder being in the chair.—Mr. F. G. Frayling read a learned paper on Infanticide, its Law and Punishment and Suggested Alterations. He held that owing to the slight possibility of being able to prove the dead child's previous "separate existence in law" and to the ordeal of the mother committed for trial on the capital charge the crime should be no longer regarded as murder, from which it differed in several particulars; a distinct offence should be created or it should be regarded as a misdemeanour or a felony, otherwise the Prevention of Cruelty to Children Act, 1904, might be modified and applied to the newly born.—Mr. Schröder felt that juries realised that they were often not dealing with the person most concerned; further, the death sentence was not a deterrent in these cases as it was never carried out.—Dr. Charles A. Mercier thought that the appearance of the accused girls led juries to exhibit a leniency to which they had no claim; he doubted if such girls were so sensitive in nature as was sometimes alleged. The jury might fancy that newly born children were hardly endowed with a conscious being, but such an idea was not present when charges of abortion were considered. The sanctity of human life must be guarded; the death penalty was a real deterrent.—Dr. W. H. Willcox regretted the present attitude of the law which led to proceedings in these cases which were almost farcical.—Mr. John Troutbeck thought that coroners were the only officials who saw what a wicked and important crime infanticide was: they had to deal with the many babies which were cast away. The criminal courts only met cases which could be traced; usually no clue was available. If violence had preceded the attempted concealment of birth the matter deserved to be treated seriously. It was notable that sober married women regarded this offence very seriously and in no case should it be treated as a matter of no great consequence.—Dr. L. Freyberger thought that the need of proving technical "separate existence" should be abolished, as it prevented the law from dealing fairly with the case; sometimes the death might have been the irresistible result of a dominating idea.—Dr. James Maughan believed that insanity of parturition was a possible, if rare, condition. The penalty for the offence of infanticide was at present inadequate in practice.—Dr. C. H. Wise thought that in this as in other matters the public suffered from the subtlety and ingenuity of lawyers. It was absurd for a hiatus to exist between procuring abortion and killing a child after birth. All punishment in legal offences should be sure and certain. The violence exhibited by mothers in some of these cases might be explained by ignorance, terror, and frenzy.—Dr. B. H. Spilsbury urged that medical men might at times have difficulty in deciding whether a child is living or dead, much more difficult would it be for an ignorant woman; evidence of viability should be considered and the presence of wilfulness examined.—Mr. F. O. Arnold held that infanticide was more prevalent than the criminal statistics would suggest, hence great care should be taken before alterations were made. The conditions of each case influenced the jury more than the strict law applicable.—Mr. Frayling having replied, the meeting was closed.

Devon and Exeter Medico-Chirurgical Society.—A meeting of this society was held on April 9th, Mr. G. L. Thornton, the President, being in the chair.—The President read notes and commented on a case of Arthritis with Purpura. The patient was a young married woman in the eighth month of her first pregnancy. There was nothing unfavourable in her family history or previous his voice and articulation were normal. He had always enjoyed perfect health and his teeth were sound. On examination a large smooth oval swelling was seen occupying the whole of the hard palate. It was the same colour as the surrounding mucous membrane; it was not tender to the touch, very firm in consistence, and slightly moveable on steady pressure. It was apparently attached by a thick pedicle to the left alveolus behind the second molar and had moulded itself to the hard palate. Without employing any anæsthetic a stout wire was passed round the tumour by means of the ordinary Wylde's polypus snare and with the exercise of moderate force the pedicle was cut through with a grating noise suggestive of bone crushing. There was practically no bleeding at the time of the operation or afterwards from the stump which was of about the size of a sixpence and healed rapidly without any complication.

Pathological report by Dr. WYATT WINGRAVE.—The tumour has the appearance of a new potato; it measures 5 by 2·8 centimetres and weighs 13 grammes. The cortical part for a depth of about five millimetres is firm and tough and incloses a hard stony core which reaches the surface at its point of attachment. In structure the cortex is composed of densely packed white fibres mingled with elongated fusiform cells (fibroblasts). The stone-like core consists of compact bone with relatively small cancellous spaces approaching the character of ivory or petrous bone. In nature it is evidently an osteoma growing from the periosteum of the maxilla to which it was attached. There was no sign of any sarcomatous tendency.

Remarks.—Such growths are by no means uncommon in connexion with the facial skeleton, for 16 specimens were shown at the Pathological Museum of the Sixth International Otological Congress, London, 1899 (Churchill's Catalogue, 1900); but this case is interesting from its clinical appearance and its admitting of so easy a removal, since such tumours not infrequently grow in connexion with the maxillary antrum and involve the orbit and other important structures.

Harley-street, W.

A CASE OF CARBOLIC ACID POISONING; RECOVERY.

By EDWARD BALM,

CIVIL SURGEON, AURANGABAD, DECCAN, INDIA.

ON Dec. 21st, 1907, at 12.30 P.M., I was informed by the father of the patient that his son, aged 19 years, accidentally swallowed 4 ounces of pure carbolic acid half an hour before (thinking it to be some other mixture he was taking). The 4-ounce empty phial, labelled "carbolic acid," was brought and shown me. The boy was ordered to be brought to the dispensary and on admission the symptoms and signs were as follows. He was cyanosed, there was a dark ring round the mouth, there was stupor, the muscles were relaxed, he was unconscious, the breathing was laboured, the pupils were contracted, the cornea was not sensitive, the skin was cold and clammy, the pulse was very thready, and frothy mucus escaped from the mouth. The stomach was washed out by the pump after administering six ounces of castor oil; 3 ounces of Epsom salts in solution were then given. After this the patient began to get worse. The breathing became stertorous, froth issuing from the mouth and the nose, the cornea was insensitive, and the pulse was only a feeble wave. I then gave him a rectal injection of 1 drachm of the tincture of digitalis and 1 ounce of rectified spirit in 6 ounces of water—i e., two hours after admission.

Finding no improvement I commenced artificial respiration and gave a hypodermic injection of 5 minims of liquor strychninæ as the breathing was very stertorous and the pulse was imperceptible. This had no effect, and when all hopes of the case were lost both by myself and the patient's relatives the idea struck me that if I were to relieve the lungs of their congestion it would help the action of the heart as well as that of respiration, and as a *dernier ressort* I removed an ounce of blood from the base of each lung by wet cupping (the blood was very fluid). Exactly four hours after the commencement of treatment and about 15 minutes after removal of the blood the cornea began to wince a little; a few minutes later the patient began to raise one of his legs, which was followed by the chattering of the teeth. Before the end of the fifth hour he fully recovered but complained of a dull pain in the head, burning sensation at the pit of the stomach, and painful throat.

The after-treatment consisted in steam inhalation for two days and a gargle containing chlorate of potassium. The patient was kept on milk and white of eggs for six days and for another six days a little gruel was allowed besides. On the twelfth day I discharged him from the hospital.

Aurangabad, Deccan, India.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on May 1st, Dr. J BARRY BALL, the President, being in the chair.

The following cases and specimens were exhibited:—

Dr. W. S. SYME: A series of Stereoscopic Photographs of patients operated on by various methods for Frontal Sinusitis, one of which showed the effect of injection of paraffin to remedy the resulting deformity.

Dr. W. JOBSON HORNE: Nine specimens from cases of Sarcoma and cases simulating Sarcoma in the Upper Air-passages. In all the diagnosis of sarcoma was suggested on clinical or pathological grounds but the large majority proved eventually to be innocent growths.

Dr. DAN MCKENZIE: A case of Mucocele of an Anterior Ethmoidal Cell in a man aged 35 years; it had been successfully opened from the nose.

Dr. J. DUNDAS GRANT: 1. A large Post-nasal Polypus growing from the maxillary antrum of a young girl. 2. A case of Lupoid Tuberculous Ulcer of the Interior of the Nose in a phthisical patient. 3. A case of Congenital Laryngeal Stridor in a boy aged three and a half years; the stridor was marked, except when breathing very quietly, and had existed all his life with hardly any improvement.

Dr. JOBSON HORNE: A case of Lupus of the Epiglottis in a girl, aged 17 years, who had no sign of tuberculosis or of lupus in other organs.

Mr. H. CLAYTON FOX: A case of Abductor Paralysis of the Right Vocal Cord, with Paresis of the Facial Muscles.

Dr. W. H. KELSON: A case of Tuberculous Laryngitis.

Dr. ANDREW WYLIE: An Angeioma of the Right Tonsil in a woman, aged 26 years.

Dr. J. W. BOND: A case of Malignant Growth, situated behind the cricoid cartilage in an elderly woman, and associated with enlargement of the thyroid gland.

Mr. A. HAMILTON BURT: A case of Septal Deflection in a consumptive patient, for discussion on the advisability of operation.

Mr. E. WARD: Subcutaneous Induration of the Neck in a woman, aged 32 years.

ODONTOLOGICAL SECTION.

Exhibition of Specimens.—Movements of the Mandible.

A MEETING of this section was held on April 27th, Mr. H. LLOYD WILLIAMS, a Vice-President, being in the chair.

The CURATOR exhibited some recent additions to the museum, including specimens of Tusks of Female Dugong, Odontome in an Antelope, Jaws of a Horse and Skulls of Lemur affected by "Swollen Head," and Tumour of Palate of 20 years' growth, apparently a fibroma undergoing malignancy.

Mr. H. W. TREWBY showed models of a case of Incomplete Eruption of the Molars.

Mr. NORMAN G. BENNETT read a paper on the Movements of the Mandible. He described how a wire framework had been made to attach to the lower teeth and to carry two small electric glow lamps in a vertical plane parallel to the median plane. One lamp was immediately opposite the right condyle, the other opposite the sulcus below the lower lip. The subject had sat, during experimentation with the apparatus, with his right side opposite a wall with a large sheet of paper pinned upon it and a convex lens being interposed was so arranged as to focus the images of the lamps on the screen. Thus the paths of the condyle and symphysis during opening of the mouth had been obtained and corresponding points for different positions of momentary rest marked on the

Reviews and Notices of Books.

The Thirteenth, Greatest of Centuries. By JAMES J. WALSH, M.D., Ph.D., LL.D. New York: Catholic Summer School Press. 1907. Pp. 436.

WE have read Dr. Walsh's book with great interest and as he himself says in his preface that there may be errors in detail in his pages, we are sure that he will not mind our commenting upon some of these in the hope that when a second edition is called for, as it ought to be, he will see fit to revise his text.

The thirteenth century was, if not the greatest, at least one of the greatest periods of human thought. In the various forms of art, especially architecture, in literary activity, in the lives of men of extraordinary intellectual power, in a burning desire for the welfare of the human race as exemplified by missionary activity and the rise of the two great orders of the Dominicans and Franciscans, it stands out like some great mountain peak above the plain. But the activities of the century did not spring into birth as novelties. They were extensions of what had gone before. And here we think that Dr. Walsh, like the Player Queen in *Hamlet*, "doth protest too much," for the impression which his book gives is that the manifold activities of the thirteenth century were the product of that century and that they were in the main ecclesiastical. For instance, on p. 21 he says, "While the universities, as is typically exemplified by the histories of Bologna and Paris, and even to a noteworthy degree of Oxford, grew up around the cathedrals. ......" This is too wide a statement. The University of Paris undoubtedly did grow out of the Cathedral School, but Bologna grew from a society of students of law who were attracted by teachers of law such as Pepo and Irnerius.

As for Oxford, the beginnings of which University are somewhat nebulous but which probably took its rise in the expulsion from Paris of "alien scholars," it cannot be said that the University grew up around the cathedral. To begin with, there was no cathedral at Oxford until 1542. The cathedral church of the diocese in which Oxford was situated was Lincoln, more than 100 miles away. It is true, however, that the Chancellor of Oxford was the Bishop's delegate.

Again, Dr. Walsh in his third chapter, which deals with the studies of mediæval students, is rightly anxious to show that scholastic teaching was not mainly concerned with hair-splitting subtleties. He lays stress on the fact that St. Thomas Aquinas taught the doctrine of the conservation of matter and energy. "The truth itself, however, had been reached by this mediæval master mind, and was the subject of his teaching to the University students of Paris in the thirteenth century." He imples, it would seem, that St. Thomas arrived independently at this fact. No one will deny the vast intellectual powers of Aquinas, yet it had been taught long before by Lucretius and his predecessors. It is fair to state, however, that Dr. Walsh says on p. 40 that the views as to the ultimate constitution of matter recently put forward by Sir Oliver Lodge and others had been taught by the schoolmen who had adopted them from Aristotle. It may be noted in this connexion that a modern observer, M. Gustave le Bon, holds that energy is not indestructible.

On p. 337 Dr. Walsh claims that it is to Innocent III. that we owe the modern city hospital as we have it at the present time, yet on the following page he says that Innocent founded his hospital on the model of the one then existing at Montpellier. Dr. Walsh allows that St. Bartholomew's Hospital in London had been founded at the beginning of the twelfth century as a priory to take care of the poor and ailing, "but at the beginning of the thirteenth century it became more frankly a hospital in the modern sense of the word." Now St. Bartholomew's was always a hospital. In fact, the hospital was founded before the priory. Moreover, the statutes of the hospital at Angers which was founded in 1175, and was therefore be it remembered under the English Crown, give directions for the sick to be sought out and admitted for treatment.

In his chapter on the great Latin hymns (Chapter XII.) Dr. Walsh in his zeal for his favourite century is led into looseness of expression. He says that most of the great Latin hymns were composed during the thirteenth century and *a few of them shortly before* it. He then goes on to say that these hymns were sung by the whole congregation and that it seems probable that "people went to church during the thirteenth century more than 100 times a year." This is quite true, for besides attending mass on Sundays and on various other feast-days an English layman was supposed to attend evensong on Saturdays and "uht song" (matins) on Sundays as well.[1] But Dr. Walsh goes on to say, "Twice a week then at least there was the uplifting cultural influence of this congregational singing of wonderful hymns that are among the greatest poems ever written and that belong to literature of the very highest order." The hymns to which Dr. Walsh specially refers—namely, Dies Irae, Stabat Mater, and the Pange Lingua of St. Thomas Aquinas—were what is technically called Proses and were only sung on special occasions. Dies Irae was sung at Requiem Masses, Pange Lingua on Corpus Christi, and Stabat Mater on the Friday in Passion Week. There were, of course, many other Proses but they were mostly of much more ancient date than the thirteenth century, and we are by no means so certain as is Dr. Walsh about the congregational singing.

We are quite in accord with Dr. Walsh's enthusiastic admiration of the Latin hymns, only we protest against his assumption that the finest were the product of the thirteenth century alone. With the exception of the Dies Irae, which, in subject, diction, rhythmical and literary skill, stands, perhaps, on a plane by itself, many of the earlier hymns are equal to any of the thirteenth century. Take, for instance, the "Veni Redemptor Gentium" of St. Ambrose, the "Vexilla Regis" and "Pange Lingua" of Fortunatus, and the Palm Sunday Hymn of Theodolphus which commences "Gloria Laus et Honor, Tibi sit Rex Christe Redemptor."

Finally, we must refer to a few slips which are evidently due to incomplete revision. On p. 63 "Anstey's Mon. Acad." should be "Mun. Acad.," the full title of the book being "Munimenta Academica." On p. 196 the name Haydn is misspelt Hayden and on p. 267 the Rev. Augustus Jessop is called "a non-conformist clergyman in England." Dr. Jessop is the rector of Scarning, Norfolk.

We have given much space to this work and have pointed out its failings, with an earnest hope that as it contains much good work, and is evidently written by one who has tried his best, it may be revised for a second edition. The thirteenth century is so great an epoch that it does not need the attribution of matter to which it can lay no claim. "Vixere fortes ante Agamemnona," and although the art, the intellectual activity, and the enterprise of the century were remarkable they were not new departures. To take one other point. Missionary enterprise and exploration were much to the fore, especially in the East. Yet as early as the tenth century the great Nestorian Church had an organisation, although in formal heresy, which stretched from Asia Minor to China.

The Major Symptoms of Hysteria. By PIERRE JANET, M.D., Professor of Psychology in the Collège de France and Director of the Psychological Laboratory of La Salpêtrière. London and New York: Macmillan and Co. 1907. Pp. 345. Price 7*s.* 6*d.* net.

THE study of hysteria has, for a time, gone out of fashion in England. The rising generation is perhaps attracted by the more tangible results of bacteriology, and possibly the health. The onset of the illness was sudden with sore-throat, headache, backache, and articular pain. Purpuric spots were noticed on the second day. She aborted on the sixteenth day of the illness, the child (a male) surviving for a few hours. The puerperium was satisfactory. Fever of a mainly intermittent type continued until the sixtieth day and during the whole of this period she suffered intense pain in all her joints. Outward manifestations were limited to the knees where there was effusion but no redness. There was œdema of the feet and legs. Nervous disturbance with occasional hysterical outbursts of a maniacal nature during the first three months rendered any movement impossible. By January, 1906, massage and movements had rendered both upper extremities normal, but in the lower there was little mobility to be obtained in any joint. In June, 1906, the ankles moved more freely and there was improvement in the left knee-joint, but the right knee-joint and both hips appeared to be ankylosed. Spa treatment was now given a trial but after two months at Bath the patient returned *in statu quo*. Early in 1907 she at last consented to movements under an anæsthetic and with great difficulty the thighs were separated, the adhesions met with being chiefly outside the joints. The knee-joints were left to a subsequent operation. In April of the same year further movements were accomplished, the left knee-joint being flexed to the full and the right to about half the normal. Slight effusion followed. The patient was now undergoing a course of heat baths and massage, and there was promise of the joints being restored to almost normal function. The interest of the case lay, in the great amount of crippling although the illness was at no time severe enough to cause real anxiety (the temperature, save on one occasion, did not exceed 102° F.); in the conjunction of the arthritis with purpura, wherein arises the question of diagnosis; acute rheumatism and septic arthritis had both been put forward in addition to the provisional one of peliosis rheumatica made at the outset. In the President's opinion acute rheumatism was negatived by the want of reaction to salicylates, by the total absence of sweating, and by the normal blood picture at an advanced stage of the illness. Against the septic theory were absence of rigors and sweats, redness of skin, and signs of fluctuation around the joints. The almost normal condition of the articular joint surfaces subsequently discovered at the operations also negatived a septic origin. Until they were better informed on the whole of the arthritic affections purpura or peliosis rheumatica seemed to be the diagnosis to receive most support in this case. As regarded treatment quinine in effervescence appeared to have had some control over the pyrexia, but alkalies, salicylates, and aspirin were futile.—After the case had been discussed Dr. R. V. Solly read a paper on Acetonæmic Conditions.

[1] Rock: Church of our Fathers, vol. iv., new edition, 1904.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 16th, Dr. R. Gordon being in the chair.—Dr. Arthur J. Hall read a paper on Some Difficulties of Diagnosis. In considering how such difficulties commonly arose he divided the causes into (1) insufficient knowledge; (2) insufficient experience; and (3) insufficient data. The third of these causes could be further subdivided according as to whether the data were really non-existent or whether they existed but had not been obtained. Allowing for a certain number of cases in which insufficient experience led to erroneous deductions it must, he said, be generally admitted that the most common source of difficulty in diagnosis was due to insufficient data and that most commonly such inefficiency was due to hurried or to careless examination. These points were illustrated by numerous examples, particularly of functional nervous disorders simulating organic disease and of abdominal cases with unusual and confusing symptoms. The paper concluded with some remarks on the difficulty of diagnosing malignant disease of the digestive tube from functional disorders and a plea was made for a more general use of the assistance which the laboratory offered to the clinician in clearing up doubtful cases.—Mr. Arthur Connell read notes of the following cases and showed the specimens: 1. Uterus Bicornis Bicollis removed by Abdominal Hysterectomy from a girl, aged 15 years, who had menstruated for two days on one occasion only. Having missed three periods she began to have great pain at the fourth period and became very ill (vomiting, abdominal colic, &c.). Rectal examination revealed a large globular mass, elastic in character, occupying the vagina and continuous with a similar tumour to the right of the mid-line. On admission to the infirmary she was anæsthetised and in the lithotomy position by the most careful examination no cervical opening could be made out, so a trocar was inserted into the globular swelling and the usual chocolate-coloured retained menses escaped. A glass tube was used as a drain. In spite of every precaution to the contrary, about six weeks afterwards the temperature rose to 99° F. and the discharge became semi-purulent so hysterectomy was performed. The one outstanding item in the case that struck all concerned was the extreme rapidity of growth of the girl. She was an in-patient for nearly three months and from being a miserable little child for her age (15 years) was discharged quite a buxom young woman. 2. Acute Obstruction in a woman, aged 53 years, due to a columnar carcinoma growing at the junction of the cæcum with the ascending colon on the posterior wall. Operation was proceeded with in two stages and death resulted from stercoræmia. 3. This was the case of a patient who was admitted for Pain in the Right Side with Pronounced Constipation which was a usual habit. A columnar carcinoma was removed from the cæcum and ascending colon. An end-to-side anastomosis with a large Murphy's button was followed by an uninterrupted recovery.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 14th, Mr. H. Shackelton, the President, being in the chair.—Dr. T. Jason Wood showed a specimen of Extra-uterine Gestation and read notes on a case of Missed Labour.—Mr. J. Phillips showed the Brain of a boy, aged eight years, with a Cerebellar Tumour with Hæmorrhage into it causing sudden death. He also read a paper entitled, "Notes on a Method of Obtaining Rapid Healing in cases of Acute Abscess." The method is based on the belief that wherever all the pus and débris could be removed from an abscess cavity and the re-collection of dead contents to act as a culture medium could be prevented practically primary healing would take place. The method consists in (1) surgically cleaning the skin about the operation area; (2) making an incision large enough to allow the finger (covered with gauze) to be introduced, with which the wall of the cavity is carefully rubbed clean and smooth; (3) packing the cavity tightly with disinfectant gauze; (4) first dressing after 48 hours, packing being removed and not reapplied but a simple gauze and wool external dressing fixed on with tight bandage; and (5) wound treated now as if simple incision. No further discharge takes place and dressing need only be done once in four or five days. Mr. Phillips's illustrative cases included glandular abscesses in the thigh and beneath the sterno-mastoid, abscesses in puerperal pyæmia, loculated mammary abscesses, ischio-rectal abscesses, and others.—The paper was freely discussed and Mr. Phillips replied.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on May 1st, Dr. W. Langdon Brown, the President, being in the chair.—Dr. Alexander Morison read a paper concerning the Nature of Heart Pain. He discussed the various theories that had been put forward to explain angina pectoris and he described the post-mortem conditions that had been found in fatal cases. He explained the phenomena of the attack and the causation of death. He concluded that angina pectoris or cardiac pain was a symptom of painful stimulation impressed upon the nerves of the heart or on the vessels immediately leaving it or running through it, which was originated by more conditions than one. It might be due to muscular spasm or to cramp causing pain much as it did in the muscles of the leg in the somatic division of the sensori-motor nervous system, or to inflammatory or degenerative changes in the vessels near or in the heart which exposed or irritated the nervous structures in the vicinity of such changes or, in similar cases, to actual changes in the nervous endowment of the organ.—Dr. David Ross showed a man, aged 30 years, with a new growth pressing on the right subclavian vein and the neighbouring lymphatics and causing marked solid œdema of the chest wall, the shoulder, and the arm. Six and a half years ago he had had a large round-celled sarcoma removed from the outer side of the right ankle. Dr. Ross also described the treatment of swallowed foreign bodies by the administration of cotton-wool and related a case in a boy aged three years.

THE summer session of the North-East London Post-Graduate College will open on May 11th. Arrangements are in progress for a vacation course to be held in September next.

Reviews and Notices of Books.

The Thirteenth, Greatest of Centuries. By JAMES J. WALSH, M.D., Ph.D., LL.D. New York: Catholic Summer School Press. 1907. Pp. 436.

WE have read Dr. Walsh's book with great interest and as he himself says in his preface that there may be errors in detail in his pages, we are sure that he will not mind our commenting upon some of these in the hope that when a second edition is called for, as it ought to be, he will see fit to revise his text.

The thirteenth century was, if not the greatest, at least one of the greatest periods of human thought. In the various forms of art, especially architecture, in literary activity, in the lives of men of extraordinary intellectual power, in a burning desire for the welfare of the human race as exemplified by missionary activity and the rise of the two great orders of the Dominicans and Franciscans, it stands out like some great mountain peak above the plain. But the activities of the century did not spring into birth as novelties. They were extensions of what had gone before. And here we think that Dr. Walsh, like the Player Queen in *Hamlet*, "doth protest too much," for the impression which his book gives is that the manifold activities of the thirteenth century were the product of that century and that they were in the main ecclesiastical. For instance, on p. 21 he says, "While the universities, as is typically exemplified by the histories of Bologna and Paris, and even to a noteworthy degree of Oxford, grew up around the cathedrals. ......" This is too wide a statement. The University of Paris undoubtedly did grow out of the Cathedral School, but Bologna grew from a society of students of law who were attracted by teachers of law such as Pepo and Irnerius.

As for Oxford, the beginnings of which University are somewhat nebulous but which probably took its rise in the expulsion from Paris of "alien scholars," it cannot be said that the University grew up around the cathedral. To begin with, there was no cathedral at Oxford until 1542. The cathedral church of the diocese in which Oxford was situated was Lincoln, more than 100 miles away. It is true, however, that the Chancellor of Oxford was the Bishop's delegate.

Again, Dr. Walsh in his third chapter, which deals with the studies of mediæval students, is rightly anxious to show that scholastic teaching was not mainly concerned with hair-splitting subtleties. He lays stress on the fact that St. Thomas Aquinas taught the doctrine of the conservation of matter and energy. "The truth itself, however, had been reached by this mediæval master mind, and was the subject of his teaching to the University students of Paris in the thirteenth century." He imples, it would seem, that St. Thomas arrived independently at this fact. No one will deny the vast intellectual powers of Aquinas, yet it had been taught long before by Lucretius and his predecessors. It is fair to state, however, that Dr. Walsh says on p. 40 that the views as to the ultimate constitution of matter recently put forward by Sir Oliver Lodge and others had been taught by the schoolmen who had adopted them from Aristotle. It may be noted in this connexion that a modern observer, M. Gustave le Bon, holds that energy is not indestructible.

On p. 337 Dr. Walsh claims that it is to Innocent III. that we owe the modern city hospital as we have it at the present time, yet on the following page he says that Innocent founded his hospital on the model of the one then existing at Montpellier. Dr. Walsh allows that St. Bartholomew's Hospital in London had been founded at the beginning of the twelfth century as a priory to take care of the poor and ailing, "but at the beginning of the thirteenth century it became more frankly a hospital in the modern sense of the word." Now St. Bartholomew's was always a hospital. In fact, the hospital was founded before the priory. Moreover, the statutes of the hospital at Angers which was founded in 1175, and was therefore be it remembered under the English Crown, give directions for the sick to be sought out and admitted for treatment.

In his chapter on the great Latin hymns (Chapter XII.) Dr. Walsh in his zeal for his favourite century is led into looseness of expression. He says that most of the great Latin hymns were composed during the thirteenth century and a few of them shortly before it. He then goes on to say that these hymns were sung by the whole congregation and that it seems probable that "people went to church during the thirteenth century more than 100 times a year." This is quite true, for besides attending mass on Sundays and on various other feast-days an English layman was supposed to attend evensong on Saturdays and "uht song" (matins) on Sundays as well.[1] But Dr. Walsh goes on to say, "Twice a week then at least there was the uplifting cultural influence of this congregational singing of wonderful hymns that are among the greatest poems ever written and that belong to literature of the very highest order." The hymns to which Dr. Walsh specially *refers—namely, Dies Irae, Stabat Mater, and the* Pange Lingua of St. Thomas Aquinas—were what is technically called Proses and were only sung on special occasions. Dies Irae was sung at Requiem Masses, Pange Lingua on Corpus Christi, and Stabat Mater on the Friday in Passion Week. There were, of course, many other Proses but they were mostly of much more ancient date than the thirteenth century, and we are by no means so certain as is Dr. Walsh about the congregational singing.

We are quite in accord with Dr. Walsh's enthusiastic admiration of the Latin hymns, only we protest against his assumption that the finest were the product of the thirteenth century alone. With the exception of the Dies Irae, which, in subject, diction, rhythmical and literary skill, stands, perhaps, on a plane by itself, many of the earlier hymns are equal to any of the thirteenth century. Take, for instance, the "Veni Redemptor Gentium" of St. Ambrose, the "Vexilla Regis" and "Pange Lingua" of Fortunatus, and the Palm Sunday Hymn of Theodolphus which commences "Gloria Laus et Honor, Tibi sit Rex Christe Redemptor."

Finally, we must refer to a few slips which are evidently due to incomplete revision. On p. 63 "Anstey's Mon. Acad." should be "Mun. Acad.," the full title of the book being "Munimenta Academica." On p. 196 the name Haydn is misspelt Hayden and on p. 267 the Rev. Augustus Jessop is called "a non-conformist clergyman in England." Dr. Jessop is the rector of Scarning, Norfolk.

We have given much space to this work and have pointed out its failings, with an earnest hope that as it contains much good work, and is evidently written by one who has tried his best, it may be revised for a second edition. The thirteenth century is so great an epoch that it does not need the attribution of matter to which it can lay no claim. "Vixere fortes ante Agamemnona," and although the art, the intellectual activity, and the enterprise of the century were remarkable they were not new departures. To take one other point. Missionary enterprise and exploration were much to the fore, especially in the East. Yet as early as the tenth century the great Nestorian Church had an organisation, although in formal heresy, which stretched from Asia Minor to China.

The Major Symptoms of Hysteria. By PIERRE JANET, M.D., Professor of Psychology in the Collège de France and Director of the Psychological Laboratory of La Salpêtrière. London and New York: Macmillan and Co. 1907. Pp. 345. Price 7*s.* 6*d.* net.

THE study of hysteria has, for a time, gone out of fashion in England. The rising generation is perhaps attracted by the more tangible results of bacteriology, and possibly the older generation is beginning to think, as Lord Kelvin is reported to have said in reference to certain points in astronomy, "There are some things we do not, and never shall, know." Many foreign observers, however, chiefly among psychologists and alienists, have devoted a great deal of attention to hysteria. In former times hysterical phenomena were regarded as supernatural, if not due to wickedness or sham; later they were attributed to some "physiological or dynamic change in the brain," as Charcot expressed it. In the present day many observers, particularly among the psychologists, have come to the conclusion that all hysterical phenomena arise entirely within the mind of the patient—in short, that they are ideogenic in origin. The book under review is by one of the ablest exponents of the psychic view and is really an abridgement of the author's larger work, entitled "L'État Mental des Hystériques," published in 1893. Dr. Pierre Janet was one of the late Professor J. M. Charcot's pupils, and it is worthy of note that he thinks M. Charcot "sought the general laws" which govern hysteria "too much in the physiological domain, which led him into a certain number of regrettable errors" (p. 17).

---

[1] Rock: Church of our Fathers, vol. iv., new edition, 1904.

The work under review is in English and consists of 15 lectures delivered before the Medical School of Harvard University. The title of the book appears unfortunate, for nobody knows precisely, and Dr. Janet does not attempt to inform us, which are the major symptoms of hysteria and which the minor. Nor does the title describe the contents of the book which deals only with one aspect, the psychological aspect, of hysteria as a whole. The work treats of the psycho-pathology of hysteria. The author states in the first lecture that pathological psychology is more easily studied in hysteria than in other diseases, partly because "the patients are easily managed, talk willingly, like to be observed, and easily lend themselves to examination," and partly "because it is only among hysterical patients that hypnotism is to be found in any marked degree." It is very doubtful, according to Bernheim, Lloyd Tuckey, and others, whether this latter statement is strictly accurate. There is no doubt, however, that the Salpêtrière School has rendered some service to science by endeavouring to bring hypnotism within the boundaries of scientific observation and utilising it for the purpose of studying morbid psychology. Dr. Janet considers that hysterical phenomena are of the nature of an auto-hypnotism, a mental abstraction, or a diminution of certain fields of consciousness. To use his own words, "Hysteria is a form of mental depression characterised by the retraction of the field of personal consciousness and a tendency to the dissociation and emancipation of the systems of ideas and functions that constitute personality." As an illustration, his observation may be mentioned that ... patients affected with marked hysterical ... number measured by the perimeter retraction of the visual fields deduct... running about and nevertheless have no difficulty ... most com... they can avoiding obstacles and in insufficient d... playing ball, ...e to hurr... patient read with ease in a way that a illustration glaucomatous ...nal nervous with a similar retraction cannot do. ...inal cases. This observation leads him to the inference that ...concluded hysterical patients must ...osing retain a *subconscious* power of visual perception, and that ...ional their amaurosis is due to a retraction of their field of ...ral *conscious* perception. Dr. Janet considers that somnam- ...tied bulism (*defining a somnambulist as an individual who thinks* ...die *and acts while he is asleep) is the most constant symptom of* ...d *hysteria, and with deference to his translator we would* Mr ...o *suggest automatism as a better word than somnam-* the ...ng *bulism and as expressing a characteristic that is certainly* die ...he *common among hysterical patients. Dr. Janet discusses* nu ...al *many different varieties of somnambulism* ... the ...lar *personality*, ...

an instance of the dissociation which plays such a large part in the author's view of hysteria the outgoing impulses which start in the ideo-motor centres of the brain and result in movement of the voluntary muscles may be mentioned. Every voluntary movement is a complex of the several muscles employed, and this complex, says Dr. Janet, becomes dissociated; the various ideo-motor impulses concerned become dissociated from one another and from the rest of consciousness.

Other mental characteristics of the hysteric are suggestibility and an exaggerated absent-mindedness. The author contends that suggestibility is a constant feature of the hysterical character, and he discusses very fully the meaning of the term suggestibility and defines it as the complete development of an idea without any "participation of the will or of the personal consciousness of the subject." In a normal individual an idea becomes manifest physically when the subject consciously acts in accordance with his idea. Thus the idea of walking is formed and the subject's conscious desire leads him to move his limbs and walk; his will and personality enter into the action. With the hysterical patient, on the contrary, the physical actions due to "suggestion" are executed subconsciously.

Dr. Janet's view is that all hysterical symptoms and manifestations are capable of a purely psychological explanation. Many of his explanations are ingenious and are as clearly reasoned as such abstruse topics can be; so clearly that the general reader can in nearly every case follow them. But we rise from a perusal of this work with a feeling, first, that his field of observation and inquiry has led him to take too narrow a view of hysteria and hysterical disorders; and secondly, that no one theory is capable of explaining the occurrence of all varieties of hysterical disorder. Undoubtedly psychology may explain a great many of these affections, but there are others, such for instance as attacks of palpitation, visceral manifestations of various kinds, and the *œdème bleu* of Charcot in which the explanation can only be sought in other parts of the nervous system. But we cannot help feeling also that the English-reading public are much indebted to Dr. Janet for having placed before them this clear and masterly review of a most difficult subject.

Diets in Tuberculosis: Principles and Economics. By NOEL DEAN BARDSWELL, M.D. Edin., M.R.C.P. Lond. & Edin., F.R.S. Edin., Medical Superintendent, King Edward VII. Sanatorium; and JOHN ELLIS CHAPMAN, M.R.C.S. Eng., L.R.C.P. Lond., Medical Superintendent, Coppins Green Sanatorium. London: Henry Frowde, Oxford University Press; and Hodder and Stoughton. 1908. Pp. 164. Price 6s.

THIS volume forms one of the Oxford medical publications. The authors have succeeded in producing an interesting treatise, for although the chief theme is a discussion of the most suitable diet for patients suffering from pulmonary tuberculosis, a secondary but equally important consideration is entered upon—namely, the economics of diet. As is pointed out in the preliminary remarks, it is of no use telling a consumptive working man earning 25*s.* a week and with a wife and family to keep to take three pints of fresh milk and plenty of meat and butter daily. Some precise information as to how he might provide himself with an adequate ...t for 8*d.* a day would be far more useful.

...he scope of inquiry decided upon by Dr. Bardswell and ... Chapman resolved itself into an attempt to determine ...e following points: (1) the best principles upon which ...etaries for consumptives should be constructed; (2) the ...tritive value in terms of proteid and total calorie value of ...o diet which is suitable for the treatment of the average ...sumptive, in short, a standard diet; (3) the best lines ...on which such an efficient dietary can be economically constructed for ... and (4) the minimum cost at which a suitable dietary can be bought retail. Inquiry carried out on these lines suggested a further series of observations upon: (1) the comparative nutritive and economic values of various foodstuffs; and (2) the comparative value of proteid from animal and vegetable sources in the dietetic treatment of consumption.

An elaborate series of investigations was made the results of which are recorded in this work and which may be studied with advantage. One of the points considered concerned the advantages and disadvantages of treating consumptives with very large diets. In the case of patients who have good constitutions, and especially good digestions, continued high feeding may produce no permanent, and indeed little or no temporary, ill effects, except perhaps some dyspnœa due to excess of body weight. In many instances, however, and notably in the case of patients with naturally weak digestions and in those who continue the high feeding for a long time after the normal body weight has been considerably exceeded, the taking of a very large diet is attended with serious disadvantages. The authors point out that one of the earliest symptoms is failure of appetite, amounting to a positiv loathing for food, usually associated with flatulent dyspepsia. The conclusion at which they arrive on this point is that the most satisfactory diet is one which represents only a moderate increase upon the diet suitable for any particular patient when in normal health.

Investigations were made as to the value of meat-free diet for patients suffering from pulmonary tuberculosis. If the case is an early one and the digestion is good then Dr. Bardswell and Mr. Chapman maintain that proteid from vegetable sources is just as valuable from a clinical point of view as proteid from animal sources; but if the disease is advanced, the digestion poor, and the appetite capricious great difficulty may be found in taking the meat-free diet and the proper amount of such diet could probably not be taken. When economy, however, is an object the necessary proteid in a dietary should be given at least in part in the form of vegetable proteid.

The remarks on the economics of diet are interesting and instructive. The free use of bread and pulses is especially advised. Some of the conclusions arrived at are founded on only a few cases and possible fallacy is fully acknowledged, but, nevertheless, the investigations are certainly suggestive and much advantage might be gained in instructing the patients in the sanatoriums for the working classes as to the form of diet which is most likely to possess the required nutritive power at the lowest cost.

The Medical Annual: A Year-book of Treatment and Practitioners' Index. 1908. Twenty-sixth year. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. Bristol: John Wright and Co. Pp. 853. Price 8s. 6*d*.

THE twenty-sixth volume of the "Medical Annual" affords evidence of the large amount of practical and progressive work which is being accomplished in connexion with medical science. On glancing through the pages of this volume the reader is at once struck by the thoroughness with which the records have been made by the various contributors.

As in previous years the work contains a few short essays by various authors on subjects which have particularly attracted attention during the past year. Dr. J. G. Emanuel, physician to out-patients, Queen's Hospital, Birmingham, writes on opsonins and vaccines and gives a clear account of the technique which is required for estimating the opsonic index. Dr. Ernest Young contributes an excellent article on the value of fæcal examination in chronic diseases. He describes the method of examination, the "trial diets," and the macroscopical and microscopical appearances which may be noted and the deductions which may be drawn from them. Professor Victor Schmieden (Royal Surgical University Hospital, Berlin) writes on treatment
and indicates the conditions for w
Dr. E. R. Morton (in charge of electrica
Hospital) describes the latest deve
therapeutics and electro-therapeutics,
attention to the orthodiagraph. The main
"Annual," however, is occupied by the "Dict
Treatment" which contains a mass of valuable and practical information, the various subjects being arranged alphabetically.

Dr. R. W. Philip (Edinburgh) writes on tuberculosis and comments on Calmette's ophthalmic reaction with tuberculin. He is of opinion that the test is delicate and trustworthy, and that it is of ready application in the case of irritable, excitable children where other methods of diagnosis may be interfered with. He has found it of particular value in the separation of a number of cases in which there was difficulty of diagnosis between tuberculosis and rickets. Mr. E. Hurry Fenwick makes some interesting observations on benign enlargement of the prostate and maintains that the best results obtained by prostatectomy have been in those patients who have used a catheter for years and in whom the prostate is enormous. He does not advise prostatectomy in cases in "which the hardness of carcinoma has so affected the capsule that it can be detected with the finger."

The present number of the "Medical Annual" well maintains the high standard which has characterised its predecessors.

London Churches, Ancient and Modern. By T. F. BUMPUS. London: T. Werner Laurie. First Series. With 30 Plates. 1908. Pp. 422. Price 6s. net. Second Series. With 33 Plates. 1908. Pp. 402. Price 6s. net.

THERE are so many associations, historical and otherwise, attaching to the churches of London, and in a special degree to the ancient churches, that a book about them such as this, intelligently written and carefully compiled, cannot fail to be interesting. But of all the ancient churches in London perhaps the most interesting to the medical man is that of St. Bartholomew the Great, West Smithfield. For this magnificent fragment of Norman and Early English architecture is the sole remaining portion of the Priory which was founded by Rahere as an adjunct to the great hospital which he founded one or two years before. All that was left of the church after Henry VIII. and his creatures had had their way with it was luckily spared by the Great Fire, an event which destroyed many a notable building but which nevertheless effected a necessary clearance of an insanitary area which afforded ample scope for the ravages of the Plague. Rahere, the founder of the hospital and the Priory, was, like so many other great men, a curious mixture of the imaginative and practical qualities of mind. Having founded the hospital, he was led by a vision of St. Bartholomew to found the Priory as well, and for some 800 years the church and the hospital have stood as a monument of the charity of the citizens of London. Rahere's dream is the subject of one of the pictures painted by Hogarth (who was baptised in St. Bartholomew's) which he presented to the hospital.

Another old City church—*Cripplegate*—also has medical associations, for it is the successor of a church which, according to Camden, adjoined a hospital for lame people and was therefore dedicated to St. Giles, the patron of cripples; while another medical link between the present and the past is that at the suppression of the Hospital of St. John the Baptist in the Savoy the beds, bedding, and other furniture were given to Bridewell and St. Thomas's Hospitals.

Among minor items of medical interest is a justly appreciative notice of Mr. Robert Brett, the well-known Stoke Newington surgeon, who was so instrumental in promoting the building of the Haggerston churches. Mr. Brett was churchwarden of St. Matthias's, Stoke Newington (one of the finest of Butterfield's churches), and another medical man, Dr. Belcher, was the first vicar of St. Faith's which was originally a daughter church of St. Matthias's. Mention is also made, in connexion with St. Michael's, Highgate, of the kindness of Mr. Gillman, a local surgeon, in sheltering the poet Coleridge under his roof, but we may remark, in passing, that the kind-hearted surgeon in so doing was only paying the same compliment to literature that Dr. Johnson was paying to medicine when he befriended in a similar manner a necessitous practitioner. The note about Oliver Goldsmith, in the description of the Temple, also reminds us that that erratic genius once practised medicine for a short time in Southwark. It is to be hoped, by the way, that his chambers in Brick-court will be spared the fate of the adjoining house which has just been condemned as an unsafe building.

But to the man who knows his London, as Besant knew it, every church—nay, every street—is crowded with memories either of some great name or some great event. Thus, St. Giles', Cripplegate, recalls Milton and Oliver Cromwell; All Hallows' Barking, Archbishop Laud and Bishop Fisher of Rochester; St. Olave's, Hart-street, Pepys; St. Andrew's, Holborn, Chatterton and Lord Beaconsfield; St. Clement Danes, Dr. Johnson; St. Dunstan in the West, Izaak Walton; Chelsea parish church, Sir Thomas More; and St. Anne's, Soho, Dr. Croft, the reputed composer of the noble psalm-tune, "St. Anne," which, by the way, is such a favourite in England that Bach's magnificent fugue in E flat is commonly, but erroneously, called the "St. Anne" fugue simply because it opens with the same notes as those that begin the English tune. By an interesting coincidence St. Anne's is nowadays famous for its *cultus* of Bach. There are besides many other churches with historical associations which we have no space to enumerate.

The disquisitions on the various architectural styles are skilfully written; and the author does full justice to the consummate genius of Wren and waxes excusably enthusiastic over his steeples which, both as to their individual beauty and their grouping, are priceless ornaments to the metropolis. He also severely criticises the so-called "restoration" of some of Wren's churches and he is very informative about the revived Gothic churches and their architects. The odds and ends of information, too, are instructive and sometimes amusing, and the particulars are brought up to date. The illustrations are very fine and the work altogether, either as a book of reference or as literature, merits the highest praise.

Guide to Diagnosis in Diseases of the Throat, Nose, and Ear. By DAN MCKENZIE, M.D., C.M. Glasg. London: Rebman. 1908. Pp. 294. Price 5*s.* net.

THIS small work is meant as an aid or guide to diagnosis in diseases of the throat, nose, and ear. There is also a chapter on notetaking and general semeiology, from which we learn amongst other things that "everyone has his own pet mirror" and that hand mirrors are "palmed off on unsuspecting and inexperienced men whenever possible." It may be wondered why the morality of the instrument maker is placed so low, indeed, why it is mentioned at all. Dr. McKenzie alludes to a method of estimating the relative patency of the nasal passages by the use of what he terms Wingrave's spiragraph; if for the sake of accuracy alone the credit of this simple contrivance belongs to Sandmann of Berlin who wrote on this matter in 1893.

Besides the main heads this little book contains a chapter on affections of the buccal cavity, which with affections of the pharynx and tonsils occupies 41 pages. As an example of the assistance afforded, speaking of diagnosis, we give that presented by Dr. McKenzie to his readers *apropos* of necrosis of the jaw: "The symptoms are those of abscess-formation, with persistent sinuses after the abscess is opened. Probing will reveal bare bone." And again in tumours of the hard palate a list is given of which some "may occur" and others are "usually due to extension." In diagnosing antral suppuration by means of the use of Lichtwitz's cannula Dr. McKenzie recommends blowing out the pus by means of a Politzer's bag. This might be a safe procedure in skilled hands but is much too liable to cause emphysema in the case of the unskilled.

This work should be of use and assistance to clinical assistants and post-graduate students who are studying diseases of the nose, throat, and ear, as affording good guidance in the investigation of patients, but it will be advisable for Dr. McKenzie to revise his next edition with great care.

LIBRARY TABLE.

A Text-book of the Practice of Medicine. By JAMES M. ANDERS, M.D., Ph.D., LL.D., Professor of Medicine and Clinical Medicine at the Medico-Chirurgical College; Physician to the Medico-Chirurgical Hospital, Philadelphia. Illustrated. Eighth edition, thoroughly revised. London and Philadelphia: W. B. Saunders Company. 1907. Pp. 1317. Price 24*s.*—This work is intended to introduce the student to the present state of knowledge of the practice of medicine in general and of the diagnosis, differential diagnosis, and treatment of disease in particular. That the book has reached an eighth edition, although the first was only published in 1897, is sufficient proof that the efforts of the author have met with the success which he deserved. The present edition has been critically revised throughout with a view to bring it into consonance with the results of modern medical research. The main features and qualities which characterised the former issues have been preserved, the practical phases of diagnosis and treatment receiving especial attention. The animal parasitic diseases have been rearranged and grouped together. These affections have been thoroughly investigated during recent years and many important results have been achieved, more particularly in relation to prophylaxis. The revision of this section by Dr. Anders has necessitated the rewriting of the articles on ankylostomiasis, dracontiasis, trypanosomiasis, and beri-beri. New articles appear on parasitic infusoria and febrile tropical splenomegaly. Among other subjects newly discussed in this edition we notice aplastic anæmia, the use of the Roentgen rays in leukæmia, polycythæmia and cyanosis with splenic tumour, Stokes-Adams disease, Vincent's angina (which has escaped introduction into the index), abortive pneumonia, chronic appendicitis without preceding acute attacks, intestinal auto-intoxication, and senile dementia. The remarks on these conditions are for the most part very brief but nevertheless the observations on differential diagnosis and treatment are adequate. Throughout the work the differential diagnosis has in many instances been tabulated, a procedure which will be found of value for purposes of reference. This text-book is certainly a good one for both students and practitioners although it possesses no marked superiority over others published in America or in this country.

La Neurasthénie: les Vrais et les Faux Neurasthéniques. By Dr. BENI-BARDE. Paris: Masson et Cie. 1908. Pp. lxv.–435. Price 8 francs.—Many men write one or two medical books, and some write three or four, in a lifetime. But Dr. Beni-Barde has completed 13 books since 1866; and he proposes to write four others, of which the titles are given in the front of the present work. If the other books be as complete compendiums of current knowledge as the one under review the author must possess an unusual power of reading and assimilating the thoughts of others. This work contains a summary of nearly all that is known about neurasthenia in France at the present time, but it makes only scanty reference to the views of contemporary German and English writers on the subject. Different examples of neurasthenia, numbering no fewer than 158, are considered in Chapters IV. to XV. In the final chapter there is an excellent summary of the views of past writers on neurasthenia. At the end of the work, in lieu of the usual "Table des Matières" found in French books, there is a summary of contents which runs to 65 pages, so that the reader may conveniently obtain almost all that he desires from its perusal. Abroad observers lean rather to the view that neurasthenia is a psychosis and they sometimes adopt the term "psychasthenia" to express the disease, although in reality this term only expresses the mental element of the neurasthenic state. The author of this work comes to the conclusion that "hydrotherapy and psychotherapy unite to form a therapeutic concord which must be considered the most beneficial and efficacious anti-neurasthenic treatment."

Egypt and How to See It, 1908. Illustrated by A. O. LAMPLOUGH. London: Ballantyne and Co. Pp. 208. Price 2*s.* 6*d.*—This is a handy little guide-book with coloured pictures which aims at indicating what is most worth seeing in Egypt and how it may be seen with the least expenditure of money and trouble. It is brightly written, erring occasionally on the side of exuberance, as in the description of the coaling at Port Said, which is described as "a very inferno of haste and efficiency." The book has useful appendices giving time-tables and other variable information, and a new edition will be published annually with this section corrected for each season. The illustrations are delicate examples of three-colour printing.

A Guide to Sick Nursing in the Tropics. By ANDREW DUNCAN, M.D., B.S. Lond., F.R.C.P. Lond., F.R.C.S. Eng., Lecturer on Tropical Diseases at Westminster Hospital Medical School and at the London School of Tropical Medicine. London: The Scientific Press, Limited. 1908. Pp. 162. Price 2*s.* 6*d.*—This little book fills a real gap in nursing literature and deserves a wide popularity amongst nurses working in tropical countries. It is apparent that its contents are frankly "lectures," and we think a little careful editing would increase their attractiveness, although this suggestion is made not in regard to what the author has to say but to his manner of saying it. Another criticism which some might make is that in several chapters the book tends to overrun its purpose and to become a guide to tropical medicine rather than tropical nursing, questions of etiology, symptomatology, and treatment being given more prominence than is received by actual nursing details. However, it is a hard matter to strike the *via media* in a work of this nature and the expositions of the etiology of various tropical infective diseases are extremely valuable, for they cannot fail to equip a thinking reader with an intelligent appreciation of the principles underlying the prophylactic measures which the author describes with clearness and authority. In these sections his enthusiasm for his subject is plainly manifest. We have found the instruction given throughout the lectures thoroughly trustworthy and have been especially impressed by the chapters on cholera, enteric fever, and malaria. Indeed, the book is well worthy the attention of a student "up for his final" in medicine. When he has mastered it thoroughly he will find himself well grounded in tropical medicine. The nurse who has done so will realise that the conditions of her work in the tropics are very different from those at home. Many little practical details are given with a view to her own comfort and safety no less than her patients'. Dr. Duncan has founded his book on a wide Indian experience but he includes African diseases in its scope. In an introductory chapter as to the nurse's "qualifications for the tropics" we are surprised that he has omitted to mention the advantages offered by membership of Lady Minto's Indian Nursing Association.

JOURNALS AND MAGAZINES.

The Bristol Medico-Chirurgical Journal.—In the March issue is published the fourth annual Long-Fox Lecture, delivered by Dr. Patrick Watson Williams, on the subject of Suppurative Disease in the Nose and Ear. Many useful diagrams are given illustrating operations on the nasal sinuses. Dr. D. S. Davies and Dr. I. Walker Hall write on typhoid-carriers and Mr. James Swain on operative interference in cancer of the pancreas: this is almost necessarily palliative and consists in some procedure of the nature of cholecystenterostomy for the relief of jaundice. Mr. C. Hamilton Whiteford records a case of successful treatment of spreading peritonitis by drainage, the Fowler position, and rectal instillation of saline solution; and Dr. David A. Alexander one of abdominal fibroma simulating splenomegaly.

The Birmingham Medical Review.—In the March number of this review Mr. Bernard J. Ward gives some statistics as to the immediate and remote results of suprapubic prostatectomy by Freyer's method. 107 cases form the basis of the report and the results are very satisfactory; the mortality of the operation, which definitely tends to fall as experience increases, may be put at about 10 per cent. The after-results are also excellent. Mr. F. Victor Milward writes on the diagnosis and pre-operative treatment of non-penetrating injuries of the abdomen and discusses the indications for laparotomy.

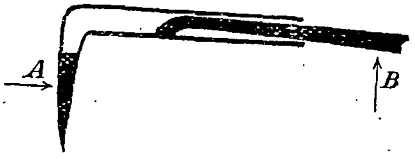
The Dublin Journal of Medical Science.—Two interesting papers on renal disease are published in the March number of this journal, one by Dr. J. Magee Finny on the prognosis and treatment of nephritis and the other by Dr. H. C. Earl on the pathology of this condition. Dr. Finny emphasises the great value of bleeding in some cases of uræmia. Mr. A. E. Wynne records two cases of nervous disease due to congenital syphilis, the manifestations being convulsions and paralysis, of paraplegic and hemiplegic type respectively. In the April number the Registrar-General for Ireland, Sir Robert E. Matheson, gives an account of the Tuberculosis Exhibition in Dublin (1907) and of the lessons to be learned from it. Mr. W. J. Greer describes the microscopical appearances of the viscera in two cases of gastro-jejunostomy for non-malignant disease, the paper being illustrated by photo-micrographs. He concludes that "though it is possible that [as a result of the operation] there may be an arrest of the original disorder, there does not seem to be any return to normal histological structure." Dr. G. Allan Crowley discusses some points in the diagnosis of scarlet fever. He assigns the septic cases to the presence of staphylococcus pyogenes, not, as has been supposed by other observers, to that of the streptococcus.

The Edinburgh Medical Journal.—In the April issue Dr. L. C. Peel Ritchie narrates some observations on the use of inoculations of bacterial suspensions. He does not appear to lay much stress upon estimations of the opsonic or, as he prefers to call it, the phagocytic index, but recommends the employment of equal weights of the different bacteria as vaccines, proportionate to the doses of Koch's tuberculin usually injected. Mr. H. Alexis Thomson treats of diverticula of the alimentary tract, with especial reference to those resulting from accessory pancreatic rudiments, one of which is depicted. Dr. Dawson F. D. Turner writes on electrolysis in medicine and surgery, Dr. F. Parkes Weber on a case of angina pectoris with aortitis, probably due to syphilis, and Dr. Alexander Walker on the provision of sanatoriums for the curative treatment of pulmonary tuberculosis among the poorer classes.

New Inventions.

AN INK WRITING-POINT ATTACHMENT FOR DUDGEON'S SPHYGMOGRAPH.

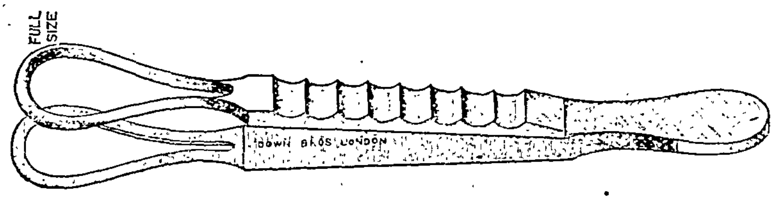
THIS simple little device for obtaining sphygmographic records in ink on a clean white paper may recommend itself to those who have found that the usual method is apt to prove rather a troublesome matter anywhere where the facilities for smoking the paper, varnishing it, and spreading it out to dry are less readily accessible than in hospital practice. It consists in a fine capillary glass tube drawn into the shape of the letter L, the longer limb of which fits on to the writing lever of a sphygmograph, whilst the shorter limb is drawn out to a fine point and serves as a writing point. Several such glass writing points can be carried in the case of the sphygmograph, together with a small bottle of writing fluid, so that the operator may have the choice on each occasion on which the sphygmograph is to be used of taking the tracing in ink on a white paper, or by the usual method on a smoked one. When the former method is to be employed all that is necessary is to select a glass writing point, thrust down its longer limb the end of the writing lever of the sphygmograph, moisten the writing point with a drop of ink, adjust the paper, and start the clockwork. The writing point, which sucks up by capillary force enough ink to write two or three tracings each six inches long, is most conveniently charged by applying to it a paint-brush wet with the ink just before starting the clockwork. After taking the tracing it is wise to drain the writing point on to a piece of blotting-paper so as to avoid clogging of the point. By this method the tracings are taken as a black line at once, thus obviating any necessity of printing the records by photography for purposes of reproduction: it does away with the necessity for soot and varnish, for the tracings are dry as soon as they are written and can be carried away at once in the waistcoat pocket. These writing-points have been made for me from my pattern by Messrs. Down Bros., Limited, 21, St. Thomas's-street, London, S.E.



A, Writing point. B, Writing lever.

J. W. SCOTT MACFIE.
Oxford.

AN IMPROVED TRACHOMA FORCEPS.



OF the two forms of forceps for the removal of trachomatous granules or "sago grains," those of Grady and Knapp, the former may be considered to cause somewhat less bruising but has the drawback, especially in unruly children, of occasionally catching in the eyelid. Messrs. Down Bros. have lately made me an improved pattern with closed ends, which gets over this difficulty with complete success.

Chepstow. J. CROPPER, M.D. Cantab.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on April 30th, Sir RICHARD DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

The following gentlemen having passed the requisite examination were admitted Members of the College:—Robert Alexander Chisolm, M.A., M.B. Oxon.; James Clark, M.D. Aberd.; Thomas Bogie Hamilton, M.B. Edin.; Eardley Lancelot Holland, M.D. Lond., L.R.C.P. Lond.; James Mackenzie, M.D. Edin.; Alexander Manuel, M.B. Lond., L.R.C.P. Lond.; Richard John Morris, M.D. Durh., L.R.C.P. Lond.; and John Norman Walker, Captain, I.M.S., L.R.C.P. Lond.

Licences to practise physic were granted to 103 gentlemen who had passed the required examinations.

The PRESIDENT announced that he had received a letter from the treasurer of the Royal College of Physicians of Edinburgh announcing the death of Dr. Charles E. Underhill, President of that College. It was resolved that a letter should be addressed to the Fellows of that College condoling with them on the loss which they had sustained.

A report was received from the examiners for the Murchison scholarship, and the same was awarded to Edward Leslie Martyn Lobb, a student of Guy's Hospital. The recipient was congratulated by the PRESIDENT. The same examiners (Dr. S. J. SHARKEY and Dr. W. HALE WHITE) moved the following proposition:—

> That a committee be appointed to consider by what means the competition for the Murchison scholarship may be increased.

The motion was carried and the following Fellows were appointed to form the committee: Dr. S. J. Sharkey, Dr. W. Hale White, Dr. Lauriston E. Shaw, Dr. H. P. Hawkins, and Dr. J. A. Ormerod.

The following Members were elected as Fellows of the College: Robert Charles Brown, M.B. Lond.; George Ogilvie, M.B. Edin.; Charles Henry Cattle, M.D. Lond.; John Elliott, M.D. Lond.; Guthrie Rankin, M.D. Glasg.; Theodore Fisher, M.D. Lond.; Robert James McLean Buchanan, M.D. Vict.; Arthur Francis Stabb, M.B. Camb.; William Henry Butter Stoddart, M.D. Lond.; Arthur Latham Ormerod, M.D. Oxon.; Walter Langdon Brown, M.D. Cantab.; Alfred Ernest Russell, M.D. Lond.; Reginald Cecil Bligh Wall, M.D. Oxon.; Thomas Wardrop Griffith, M.D. Aberd.; and Leonard Stanley Dudgeon.

The following communications were received: 1. From the secretary of the Royal College of Surgeons of England reporting proceedings of its Council on April 9th. 2. From the secretary of the Royal College of Surgeons in Ireland thanking the College for its letter and resolution of March 20th. 3. From the registrar of the University of Wales (new Faculty of Medicine) inviting the College to appoint a representative to serve as a member of the Medical Board. The invitation was accepted and it was left to the President to nominate a Fellow to act as a representative. 4. From the secretary of the Society of Arts, giving notice of the award of the Swiney Prize, jointly by the Society and the College, in January next, for the best published work on Medical Jurisprudence.

A report was received and adopted from the Pharmacopœia Committee, which was appointed on Jan. 30th, 1908, in response to an invitation to the College from the President of the General Medical Council to assist in the revision of the British Pharmacopœia of 1898.

The PRESIDENT then dissolved the Comitia.

VICTORIA UNIVERSITY OF MANCHESTER.—The council of the University having decided on the appointment of a second professor in the department of medicine, one of the chairs will be devoted to clinical medicine and the other to systematic medicine. Dr. Graham Steell, now professor of medicine in the University and senior physician in the Royal Infirmary, will hold the chair of clinical medicine, and Dr. George R. Murray, who until recently held the Heath professorship of comparative pathology in the University of Durham, has been appointed professor of systematic medicine. Under the agreement entered into between the University and the Royal Infirmary Dr. Murray becomes on his appointment a member of the honorary staff of the Royal Infirmary. It is expected that he will undertake the duties of the chair in the University at the beginning of next session and at the infirmary when the new buildings are opened.

THE LANCET.

LONDON: SATURDAY, MAY 9, 1908.

General Practitioners and Consultants.

DURING the past few weeks a discussion has been going on in the columns of THE LANCET on the question of the division of the operation fee between the operator and the general practitioner. It has been recognised widely that the fee of the general practitioner who takes a patient to a consultant for an operation is altogether out of proportion to the fee that the consultant charges for the operation which he performs. Inasmuch as the functions performed by the two differ greatly in degree a great disparity is not unreasonable; but it is held by many medical men in general practice that the large amount of the fee charged for the operation may prove, and in fact often proves, a great strain on the finances of the patient, with the result that the fees already owing to the general practitioner cannot be paid. We venture to think that there is a modicum of basis for this complaint and any satisfactory arrangement which could be made in the direction of equalising the amount received by the general practitioner and by the consultant would be deserving of adoption, but the arrangement must be in full accord with the ethics of the profession.

There is a modern practice, happily little heard of in this country, which is known by the name of dichotomy. The word, indeed, is an old word and has several scientific applications, but so far as we are aware the recent special medical meaning has not yet found its way into the dictionaries. This special application of the word arose in France where the practice to which it is applied also appears to have originated. By dichotomy in its medical sense is meant a division of the consultant's fee between the general practitioner and the consultant. The general practitioner takes or sends a patient to a consultant who advises the performance of an operation for which the operator charges, let us suppose, a hundred guineas. The patient agrees, undergoes the operation, and pays the fee. Immediately on receipt of the fee the surgeon sends a cheque for half the amount to the general practitioner who sent the case to him. Sometimes the fee is not divided equally but the exact proportions in which the division is made do not affect the matter. The patient, who pays the fee, knows nothing of this division; he imagines that the whole of the operator's fee is for the operator and the fact that the general practitioner who introduced him to the consultant gets a portion of the fee for the operation is utterly unknown to him. The share of the fee given to the general practitioner is not given for assistance at the operation or for after-treatment but wholly and solely for the introduction of the case. This is dichotomy pure and simple, and if we may believe reports it is a practice very widespread on the continent of Europe and in the United States, and it is rumoured that it is by no means unknown in this country. The essence of dichotomy is that the division of the fee is not known to the patient and this absence of knowledge on the part of the patient would suffice to bring the practice within the scope of the Secret Commissions Act. The influence of dichotomy has been very harmful; it appears to be certain that its tendency is to lead to the performance of unnecessary operations, however excusable it may have been in its origin. Dichotomy can in no wise be defended. It is therefore satisfactory that dichotomy has been condemned in those countries where it is especially rife and it is to be hoped that it will not spread here. We cannot but look upon dichotomy as very much on a level with the receiving of fees from undertakers or instrument makers who have been recommended.

A method has been suggested by Dr. F. W. FORBES-ROSS in the correspondence in our columns which is certainly less objectionable than dichotomy, from which it differs in several important respects. By this method the fee for the operation is divided into three parts, the operator takes two-thirds and the general practitioner takes the remaining third; and in return for this share of the fee he assists at the operation and undertakes a portion, perhaps the major portion, of the after-treatment. So far there is little to distinguish the method from dichotomy, except that certain assistance is rendered in return for the fee, but, and this is most important, the patient is informed of the arrangement made, and this very fact of the knowledge of the patient of the intended division of the fee certainly removes the arrangement from the category of dichotomy. There is a further point on which Dr. FORBES-ROSS insists, and that is that if only a part of the fee can be paid at the time the consultant and the general practitioner must share in the same proportion as if the whole fee had been paid. There is, however, this to be said, as pointed out by Mr. EDWARD DEANESLY, that this third of the fee should be paid directly to the general practitioner by the patient and it should not be paid by the operator after he has received his fee. If the surgeon pays the third to the general practitioner there is always the risk of the transaction not being made clear to the mind of the patient and then the practice falls into the same group as dichotomy. There is another method which is widely adopted and it is one which appears to us to have many points in its favour. The patient is often anxious to know what is the total amount of the expense to which he will be put, and the general practitioner, after consulting the operator, mentions a fee which is to include the operator's fee, his own fee, and the fee of the anæsthetist. The general practitioner receives the fee from the patient and hands to the operator the portion payable for the operation. This is often more satisfactory for the patient and it appears to us to be perfectly ethical. It has certainly nothing to do with dichotomy. Whatever arrangements are made it is essential, as we have already said, that the patient should be informed if any division of fees takes place. The general practitioner is generally in a position to know the amount of fee which will not be oppressive to the patient and yet which will be sufficient to remunerate those who perform and assist at the operation and in the after-treatment.

Scopolamine as an Analgesic.

THIS substance either alone or combined with morphine for some years has been adopted for anæsthetic purposes in several of the continental clinics. Some surgeons have used the method as a means of lessening the quantity of the general anæsthetic which they give to the patient at the time when the actual operation is in progress. Many have tried scopolamine-morphine anæsthesia for surgical work but have found it uncertain and at times insufficient when severe operations had to be undertaken. In obstetric practice, however, analgesia rather than anæsthesia is commonly aimed at and GAUSS has published a number of cases in which the scopolamine-morphine combination has been adopted by him with marked success. Dr. W. AYRES, in a paper read before the Stourbridge District Medical Society, describes the method and the condition which GAUSS has designated "dämmerschlaf" (twilight sleep), and which is characterised by insensibility to painful impressions and complete loss of memory of all that has occurred while the state has lasted. He points out that there have been a number of fatalities under scopolamine and morphine and these he has investigated, coming to the conclusion that they have arisen through the use of untrustworthy drugs.

Commercial scopolamine frequently contains impurities, such as atroscine, a body the therapeutic action of which is not the same as scopolamine. It is also important to remember that scopolamine is obtained from various plants, and although it has not been actually proved to be so it is possible that the samples vary in action according to the source from which they are derived. If this be so it is probably due to the presence of varying quantities of other alkaloids, the commercial scopolamine being in fact a mixture of alkaloids giving varying results. Although therapeutically quite distinct the alkaloidal bodies scopolamine, hyoscine, cocaine, and atropine are chemical isomers possessing the empirical formula $C_{17}H_{23}NO_3$. KOBERT asserted that scopolamine and hyoscine exert practically the same physiological action, but Dr. AYRES points out that the scopolamine derived from scopolia is a mixture of hyoscine and atroscine, and is obtainable in greater quantity from this source than is hyoscine from hyoscyamus. Hence the greater cheapness of the scopolia derivative. Although hyoscine and scopolamine are chemically identical it does not follow even when they are pure that they will give similar physiological effects, and when impure their results therapeutically may be quite discordant.

Dr. AYRES insists upon various points in GAUSS's technique as essential if success is to be obtained and the woman in labour is to fall into the semi-unconscious state which besides affording analgesia insures no memory of pain and complete freedom from the hysterical state which at times is liable to be evinced in parturition. Two separate sterile solutions are used: a 0·03 per cent. aqueous solution of crystalline scopolamine hydrobromide and a 1 per cent. aqueous solution of morphine. The first injection is given when the pains are becoming severe and frequent and should consist of from 1 to 1·5 cubic centimetres of scopolamine solution (= 0·30 to 0·45 milligramme), with 1 cubic centimetre of morphine (= 0·01 milligramme). In half an hour the patient is shown some object—e.g., a pair of scissors; and again after another half an hour she is questioned as to whether she remembers the scissors. If she does not it is assumed that she was in the state of "dämmerschlaf" when shown the object and no further injection is needed until future testing made in each case with a different object to avoid accumulation of sense impressions reveals that the "twilight sleep" is passing off. Before each manipulation the patient is tested and fresh injections are given as the indications appear to warrant them. The subsequent injections consist of 0·5 cubic centimetre or 1 cubic centimetre of the scopolamine solution according as the 0·5 cubic centimetre does or does not produce the "dämmerschlaf" persisting for two hours. GAUSS does not repeat the morphine, since it interferes with the expulsive labour pains. As a general rule, four injections made at the interval of an hour will suffice, although a two or even four hours' interval will prove sufficient to maintain the "dämmerschlaf" until the birth of the child. The total amount of the drug used may be accepted as upon an average 0·75 milligramme, although as little as 0·3 milligramme and as much as 1·2 milligrammes may be required. Great stress is laid upon avoiding all noises (GAUSS stops the patient's ears to prevent the infant's cries reaching her), upon the use of fresh solutions, and upon obtaining the "dämmerschlaf" state by small doses and slowly. Dr. AYRES quoting GAUSS asserts that the usual causes of failure are: (1) forcing the effect by too large and oft-repeated doses which give rise to weak pains, rapid and irregular pulse, hallucinations, excitement, failure of the expulsive power of the abdominal muscles, and asphyxiation of the fœtus; (2) too little time before the birth for preliminary injections; (3) beginning too early in the labour—the pains should return every five or six minutes and last for 30 seconds before the first injection is made; and (4) being induced by the patient's cries to repeat the injections instead of being guided entirely by the memory test.

It has been asserted that this method delays labour but GAUSS's experience does not appear to bear out this contention. Dr. AYRES seems to be satisfied that provided the morphine is given in a sufficiently minute dose neither the uterine fibres nor the abdominal muscles become atonic. The effect upon the mother is stated to be, upon the whole, satisfactory, although the action of scopolamine upon the heart is one with which the accoucheur may have to reckon. To the child, however, more serious results occasionally follow unless the most heedful watch is kept upon the infant throughout the labour and for some days afterwards, since the "dämmerschlaf" of the mother finds its counterpart in a peculiar intoxication in the child. The breathing is extremely slow, cyanosis may appear, and the infant's heart's action is correspondingly hampered. However, as GAUSS's figures show, if the child is properly watched and measures are taken to insure due lung expansion, the mortality is not unduly great. It is unwise, we are told, to adopt GAUSS's method in large maternity hospitals or private practice unless there is ample help at hand to insure attention being given both to the mother and to the infant. Dr. AYRES referred also to Dr. ABBOTT of Chicago who has employed hyoscine hydrobromide, morphine hydrobromide and cactin. We have noticed this combination and need only add that Dr. Abbott's experience has led him to form a favourable opinion of it in his surgical practice.

Nursing in the Paris Hospitals.

The question of efficient nursing in the Paris and in the French hospitals generally has been from time immemorial complicated by religious disputation. It is quite a mistake to imagine that it is only under the Republican form of government that the idea of secularising the hospitals arose. So far back as the year 1505 the Parliament issued a decree dated the 2nd of May of that year placing the oldest of the Paris hospitals, the Hôtel Dieu, in the hands of a commission of eight lay administrators. This was done because of the disorder that prevailed; no accounts were kept and scandals arose between the monks and the nuns who used to manage the hospital. Again, under Louis XIV., and by order of the King, the management of the Salpêtrière, Bicêtre, and Pitié Hospitals was taken away from the priests and handed over to secular officials. Then under Louis XVIII., at a period of monarchical and clerical reaction, by the decree of June 28th, 1819, secular dispensers were appointed instead of the sisters or nuns in some of the pharmacies and in the management and keeping of accounts (*économat*) of the Paris hospitals of La Charité, Saint-Antoine, Enfants Malades, Enfants Trouvés, Necker, and Cochin. In 1833 the Sœurs de la Sagesse were replaced by secular nurses at l'Institution Sainte-Périne, then at the Maison de Santé, the Hôpital des Cliniques, du Midi, and of La Maternité. Therefore, leaving out of consideration other countries such as Germany, Great Britain, the United States, and even Portugal and Russia, the principle of the secularisation of hospitals was admitted, and to some extent practised, before the Republican form of government was definitely established in France. There is consequently no reason why this question should not be decided on its own merits without introducing political prejudices and animosities. If it is wrong, then all political *régimes* have a share in the wrong.

The French law on associations, arising out of the Dreyfus affair, has, however, greatly accelerated the process of secularisation and, of course, the present period of transition occasions many complaints. In another column Dr. J. Dardel of Paris gives voice to some of the lamentations that are the inevitable accompaniment of all changes, even if they be beneficent. Undoubtedly the present state of affairs lends itself to criticism. Dr. Dardel justly complains of the life led by the nurses, of their dirty, dismal dormitories, often situated in garrets, the scanty furniture, and the want of air and comfort. If he will turn to The Lancet of June 13th, 1891, p. 1332, he will find a full confirmation of his assertions. Our Special Sanitary Commissioner then supplied us with an account of the insanitary condition of the Hôpital de la Pitié and M. D. Widhopff, well known for his art contributions to the illustrated press, drew for us pictures of the nurses' garret dormitories. In denouncing this state of affairs our commissioner then said that "it was justly observed by several persons at the hospital that prisoners in a State gaol have much better accommodation than the free and trained professional nurses of the Hôpital de la Pitié." To this, however, we are pleased to add that it was subsequently decided to rebuild this hospital; indeed, we received thanks at the time for having helped to awaken public opinion on the matter and having aided in bringing about this much-needed change. Of course, while they are so badly lodged and cared for it will be difficult to secure the services of a high-class of nurses. But the position is improving and many of the present evils are due to the old system which is now so rapidly disappearing. We are asked, however, what object Paris had in effecting "so sweeping a reform" which Dr. Dardel qualifies as "merely a political move." The object was fully described in The Lancet of Dec. 20th, 1890, p. 1355. We then quoted the decision of the Paris Municipal Council adopted in 1877, which stated that its object was:—

> 1. To secure for the hospitals a staff of nurses who should be more competent, better educated, and who would become good superintendents to control wards in the stead of the sisters belonging to the religious orders. 2. To afford inhabitants of the towns who wish to exercise the profession of nursing means of obtaining thorough professional instruction, so that they might take the place in private families of the sisters who act as nurses. 3. To enable mothers of families to obtain the knowledge necessary for nursing the sick, so that they might skilfully second the efforts of the doctor whenever any of their relatives fell ill.

In keeping with this resolution the first school for training nurses was opened at the Salpêtrière on April 1st, 1878, and another on May 20th at Bicêtre. In 1880 a third school was inaugurated at La Pitié. We gave at the time a full account of the curriculum. To-day, however, the complaint is made that though the technical instruction has borne fruit only a low class of nurses have been recruited whose morality and probity are not above reproach. This is true to some extent, though there is a political temptation to exaggerate the complaints. In any case this grievance is in a large measure due to the system that prevailed when the *sisters were serving* in the Paris hospitals. Much has been said about the wonderful devotion of these sisters and all the unpleasant and hard work which they did in personally tending the sick. This likewise was, to a certain extent, mere romancing for a political purpose. As we pointed out at the time in 1878, before the present secularisation of the hospitals commenced, there were only 485 sisters serving in the Paris hospitals, and there were already 279 secular head nurses or superintendents. The real trouble arose from the fact that these sisters did not change the bed-clothes, did not dress wounds, did not wash and see to the personal comforts of the patients; all the really hard and unpleasant work was left to the 2207 secular under-nurses or servants. The sisters did organise the partition of food, superintend linen, and maintain discipline in the wards. The sisters, in a word, were the matrons, and by monopolising the best positions on the nursing staff destroyed the spirit of emulation and prevented higher-class candidates presenting themselves for this service. Therefore the most incompetent of provincials who could not even speak French served in the hospitals. They were inadequately paid and left as soon as they had acquired enough experience to get better wages elsewhere. But to-day the salaries even of the mere scrubbers and scullery-maids have been raised and attempts are made to improve the social standing and position of those who seek to become trained nurses. Much remains to be done yet. Quite recently[1] our Paris correspondent described the inauguration of a building with two wings at the Salpêtrière, where 75 pupil nurses will each have a private room and live in decent comfort. At the end of two years' training, practical and theoretical, they will, on passing the examinations, be given board, lodging, a uniform like that of English hospital nurses, and £24 a year. These young women will be under the care of a matron, will not be allowed to go out except with members of their own families, and the respectability and moral training which the sisters were supposed to give will not be wanting in this new nurses' college. But, of course, many more such establishments are needed before the evil repute in which the profession of nursing had fallen in France is fully removed. In time it will be realised that sisters no longer block the way to the highest posts in the nursing profession. In time better housing, better uniforms, and better pay will raise the dignity of the calling, and more severe discipline could then be enforced in regard to personal conduct and especially in respect to the acceptance of gratuities. In the olden days when a patient was left to the mercies of some uncouth country girl who was only paid 12*s.* a month wages the friends of the patient naturally offered small sums of money to these servants so that they might try to be more gentle and attentive. On the other hand, the higher and more educated candidates who desired to qualify as trained nurses objected to the society of the poor uneducated women who were willing to do all the dirty work for so little pay. But this state of affairs, which existed when the sisters were supreme, is now altered though the evil reputation which it engendered does not fade away so rapidly. Still, a better time is coming and the evils surviving to-day are less than those that prevailed yesterday.

Annotations.

"Ne quid nimis."

THE CERTIFICATION OF OPTICIANS.

THE Worshipful Company of Spectaclemakers has recently published a syllabus of the subjects upon which those who are desirous of obtaining their certificate of competence in optical work shall be examined. The company is by no means of recent institution. It received a charter from Charles I. in 1629, but was in existence long before that date. The records which were formerly in its possession were probably destroyed in the Great Fire of London. It has a considerable number of members but its total corporate income is only about £1200 a year. The company has a master and wardens with eight assistants, a clerk and an assistant clerk, an interim trade council, and a board of examiners composed of Mr. W. H. E. Thornthwaite, Dr. R. T. Glazebrook, D.Sc., F.R.S., Dr. G. Lindsay Johnson, Dr. Mullineux Walmsley, D.Sc., F.R.S.E., Dr. C. V. Drysdale, D.Sc., and Mr. J. T. Gradon, M.A. Oxon. The company holds three examinations: the first is the preliminary, the second is the final examination in visual optics and sight testing, and the third is the final examination in advanced optics and scientific instruments. The preliminary examination consists of five sections and includes a written examination in arithmetic, algebra, geometry, and trigonometry, a *vivâ-voce* examination in general optics embracing such subjects as light, the laws of reflection and refraction, prisms, the use of the spectrometer, the various forms of lenses, the principle of the ophthalmoscope, optometer, ophthalmometer, perimeter, phorometer, and the mode of using test type and astigmatic chart, a practical examination in the optical analysis of lenses, the marking of edging and of other lenses for setting, centering, and decentering, and, lastly, a practical examination in frame fitting and measurements and in the reading and filling ophthalmic surgeon's prescriptions. Every candidate must have attained the age of 18 years before presenting himself for this examination and must pass it before proceeding to one or other of the two final examinations, for each of which the company grants a diploma. One of these final examinations is upon advanced optics and scientific instruments and the candidate is required to possess a thorough knowledge of the principles of construction of various optical and meteorological instruments such as the camera, microscope, telescope, and barometer, the examination being both written and *vivâ voce.* Up to this point we can only express our admiration of the excellence and completeness of the education which the candidate must have undergone if the answers to questions on all these subjects are maintained at a high level. We should have thought that there was enough in these multifarious departments of knowledge to engross the faculties of the majority of the future spectacle-makers. The second final examination for which the company grants a diploma touches more debateable ground. The title of this examination is "final examination in visual optics and sight testing." It consists of three sections: a *vivâ-voce* examination in visual optics, a written examination in visual optics, and a practical examination in the adaptation of lenses to correct errors of vision. On examining the syllabus of the requirements of the candidates we find that they are in the first place expected to answer questions on lenses, prisms, and frames, to which no exception can be taken. If the optician is to supply lenses ordered by the ophthalmic surgeon he must be familiar with the various forms and combinations as well as with the mode in which they should be mounted. Next, a knowledge of the general structure of the human eye is demanded with an explanation of cardinal points, curvatures and refraction indices of the media, constants and dimensions of the schematic and reduced eyes, and of the angles α and γ, and the identification of parts of the eye in models and charts. All this may be conceded as part of the education of a highly educated optician. The next paragraphs in the syllabus are those to which we demur. We give them in full; and questions on them could, we submit, only be satisfactorily answered by a man who had gone through the ordinary curriculum for a medical degree. "Static and dynamic refraction of the eye. Accommodation and convergence. The movements of the eyeball and muscles employed. The near and far points. The range and amplitude of accommodation and convergence. The course of light through the media of the eye alone and modified by spherical and cylindrical lenses and prisms. Emmetropia, hypermetropia, myopia, astigmatism, anisometropia, aphakia, presbyopia, asthenopia, amblyopia, orthophoria, heterophoria, strabismus, diplopia. The fields of vision and fixation. Stereoscopy. Chromatism of the eyes—tests for the same. Colour vision and blindness." In addition the candidate must be familiar with the ordinary instruments in common use for determining the refraction and muscular balance of the eyes; the optometer, ophthalmoscope, ophthalmometer, phorometer, rotatory prism, and other muscle-testing appliances. In the *vivâ-voce* examination a prominent place is given to *muscle testing.* Our contention is that this final examination covers ground that does not belong to spectacle-makers, however highly educated they may be; that it demands far more, and a different kind of, knowledge than can be obtained from books or than can be deduced from the construction or properties of instruments. Questions put upon this syllabus must either be answered in a very loose and perfunctory manner, in which case the knowledge is useless, or if replied to satisfactorily the candidate is fitted for a medical degree and is endeavouring to evade the other branches of a medical examination and to enter the ranks of the medical profession surreptitiously. Our advice, in view of future difficulties and complications, is that a large portion of the syllabus for the final examination in visual optics and sight-testing should undergo revision and that certain subjects should be withdrawn. The subjects of examination as here laid down if thoroughly mastered would be creditable to a wrangler on the theoretical side and would far and away outstrip him in the mechanical aspect of optical science.

INFANT MORTALITY IN ENGLAND AND WALES, 1907.

IN connexion with the awakening of public attention to the neglect and waste of infant life in the United Kingdom it is satisfactory to note that the rate of infant mortality in England and Wales during 1907 did not exceed 118 per 1000 births registered. This rate was considerably below the rate recorded in any previous year since the commencement of civil registration in 1837. The nearest approach to so low a rate of infant mortality was 128 per 1000 in 1905. There has, moreover, been a marked decline in the English rate of infant mortality since the beginning of the present century. During the ten years 1891–1901 the mean proportion of deaths under one year to births was equal to 154 per 1000, whereas the mean proportion fell to 134 per 1000 in the seven years 1901–07. There is great difficulty in determining how much of this decline of infant mortality may be attributed to increased care of infant life and to more effective sanitary supervision, and how much may be due to recent favourable meteorological conditions—to lower summer temperatures or to more frequent summer rainfall. It appears that the mean temperature at Greenwich during the summer quarters of the ten years 1891–1900 was 61·9° F. and that the mean annual amount of rain measured during the same quarters was 6·1 inches on an average of 39 days; while in the summer quarters of the last seven years (1901–07) the mean temperature did not exceed 60·9°, and the mean rainfall was 5·8 inches measured on 34 days. Thus an average deficiency of 1·0° in the mean summer temperature during the last seven years has been accompanied by a slight decrease of rainfall, on an average of somewhat fewer days. There appears, therefore, to be no sufficient reason for attributing any considerable proportion of the recent decline of infant mortality in England and Wales to exceptionally favourable meteorological conditions during the last seven summers. The satisfactory fact remains that the rate of infant mortality in England and Wales during last year did not exceed 118 per 1000, was far the lowest rate on record, and showed a decrease of 20·3 per cent. upon the mean rate in the ten preceding years, 1897–1906. Having regard to the recent legislation for facilitating the early notification of births to sanitary authorities, it is interesting to note that in Huddersfield, under the influence of the special system of birth notification, authorised by a local Act, and of exceptionally energetic action by the local sanitary authority, the rate of infant mortality within the borough declined to 97 per 1000 births, and showed a decrease of 28·1 per cent. upon the mean rate in the ten preceding years, against an average decrease of 20·3 per cent. on the whole of England and Wales. This naturally raises the interesting question as to the proportion of the decrease of infant mortality in Huddersfield during last year that may be attributed to the prompt notification of births to the medical officer of health and to the facilities thus afforded for promoting increased care of infant life.

HUMAN INFECTION FROM BOVINE TUBERCULOSIS.

IN his annual report for the year 1907 Dr. J. P. Watt, the medical officer of health of the county of Aberdeen, makes reference to two cases of tuberculous meningitis, which from their bearing on the question of the possibility of conveyance of bovine tuberculosis to the human subject through the infected milk of a cow and from the exhaustive examination carried out by Dr. J. Adams of the Pathological Department of the University in connexion with them appear to be of special interest. Attention was directed to them through a suspicion arising in the mind of the medical attendant as to the second case being one of cerebro-spinal fever. The cases occurred in the children of a farm servant who in May, 1906, had gone to a small farm in the country, which farm was occupied by the tenant only in summer and was managed by a grieve and his wife. This man's family consisted of three girls, aged nine, six, and four years. The milk was obtained from a cow which was the only one on the farm and which had been there for about four years. The cow had a calf but no suspicion seems to have attached to this. The eldest girl died on Jan. 7th, 1907, after an illness lasting three weeks with symptoms of tuberculous meningitis. The youngest was taken ill in the beginning of March and died on the 18th with similar symptoms. As cerebro-spinal fever had by this time broken out in the county it was thought advisable to verify the diagnosis by a post-mortem examination. Tuberculous meningitis was found and a caseous gland in the mesentery. The cerebro-spinal fluid was drawn off aseptically and from it a pure culture of the tubercle bacillus was indirectly obtained. Clinical examination of the cow revealed a nodular mass on one of the hind-quarters of the udder, and the milk itself was found to contain tubercle bacilli. The cow was subsequently killed and a post-mortem examination was made. Extensive tuberculosis was found, especially in the pleura, peritoneum, glands, and udder. From the milk and glands pure cultures of the bacillus were obtained. The bacilli from these and from the cerebro-spinal fluid of the child were then compared and from their microscopical, cultural, and pathogenic characters the opinion formed was that they were both of the bovine type. No family history of tuberculosis was traced either on the father's or the mother's side.

THE RELATION OF SUICIDE TO SEXUAL FUNCTION IN WOMEN.

IN the *Annales Médico-Psychologiques* for March and April of this year Dr. Alexander Pilcz, in a paper discussing the diseased conditions met with in the post-mortem examination of the bodies of persons who have committed suicide, brings forward some interesting facts illustrating the influence of the sexual life on the development of suicidal impulse in women. From the records of the Medico-Legal Institute in connexion with the University of Vienna he has obtained detailed information with regard to 256 cases of suicide by women within the child-bearing period. In 51 of these cases (19·2 per cent. of the series) the women were pregnant, and Dr. Pilcz remarks that this figure is probably an under-estimate, for he has excluded from his list of suicides several doubtful cases in which pregnant women died from phosphorus poisoning; this drug is in popular repute in Vienna as a means of procuring abortion, and most of the deaths from it are doubtless due to its use for this purpose, but it is highly probable that in some of the instances it may have been taken with suicidal intent. The exact stage of pregnancy was noted in 47 cases, 15 falling in the first month, 7 in the second, 7 in the third, 8 in the fourth, 2 in the fifth, 4 in the sixth, and the remaining 4 in the ninth month, so that nearly 60 per cent. of the suicides occurred in the first four months of gestation. This result is, of course, in accord with what has been observed regarding other disturbances of nervous function which are notoriously more frequent and more severe in the earlier than in the later months of pregnancy. Of the cases of suicide by women within the period of active sexual life 36 per cent. occurred at the time of menstruation, this being almost exactly the same proportion as was found by Heller in his smaller series of cases.[1] Dr. Pilcz further ascertained that in two-thirds of the cases occurring during menstruation the cycle was in its initial phase; and it may be observed in this connexion that a similar relation obtains in attempts to commit suicide, which are specially prone to occur at the premenstrual epoch. In 322 cases in which the records gave sufficient information on the point, 71 (21·73 per cent.) were found to present morbid conditions of the genital organs: gonorrhœa and uterine fibroids were the forms of disease chiefly met with.

APRIL'S ABNORMAL WEATHER.

THE appended figures show, in part, the extraordinary weather of last month but they fail to show the abnormal lowness of the temperature for nearly a week towards the end, neither do they differentiate between the measurements of rain and snow. They show enough, however, to prove that the weather was very cold for the time of the year and also that in most localities, especially in London and central and south-eastern England, the divergence from the average during the daytime was greater than at night. During the extra cold period that set in about the 20th the temperature of the afternoons was lower than during a normal afternoon in January in many parts of the kingdom, while in some parts of Scotland and the north-east of England the frost of the nights was more severe than any experienced in those regions so late in the spring since the establishment of the Meteorological Office more than 40 years ago, and in some places more severe than any frost of the past winter. Minimum readings below 20° by the screened thermometer were registered over a very wide area, while at Braemar there was a reading of 10° in the screen and one as low as 4° on the grass. Snow is, of course, often experienced in slight fleeting showers in April in one or more parts of the country and there are records of heavy falls both in the north and south quite late in the month. There is, however, no authentic record of such an abnormal quantity of the wintry element over such a large area of England so late in any April of the past. Had the snow been dry and light instead of wet and heavy, and had it fallen on a dry instead of on a wet soil it would have had an average depth of about two feet over many hundred square miles of the southern half of England. The remarkably sudden change from winter to summer that surprised most parts of England as soon as April had given place to May was almost, if not quite, as abnormal as the preceding cold. Within a week of temperatures lower than those of an average mid-winter, London and the inland parts of England generally were called upon to endure a heat greater than that of an average July and August. In London the whole of the three summer months last year gave but four warmer days than May 1st. The official maximum temperature registered in St. James's Park on May 1st was 75° F. and that on the following day 74°. But just as the human organism was beginning to grow accustomed to summer heat the thermometer went down with a rush to the level of March and the hot sunshine gave place to heavy rains and cold winds.

ANIMATED PHOTOGRAPHY IN NATURAL COLOURS.

THE kinematograph is now universally recognised as a means not only of amusement but of instruction. We need only refer, for instance, to the article by Dr. H. Campbell Thomson which appeared recently in our columns.[1] Hitherto of course, the reproduction of any colour in a kinematograph projection has been impossible except by the laborious method of hand-colouring the films, and as each picture on the film is only of about the size of a postage-stamp it is obvious that to hand-colour the photograph of a carpet or of a highly coloured insect or bird by hand upon this scale is impossible. An invention has now been brought forward by Mr. G. Albert Smith, F.R.A.S., for reproducing in natural colours photographed objects upon a screen, and a demonstration was given at Urbanora House, Wardour-street, on May 1st. Mr. Albert Smith in his interesting inaugural address gave a rough idea of the theory of his system in the following words:—

> When I show you a wax phonograph or gramaphone "record" and observe that it is a band of music or the voice of a singer, you are aware that it is in reality an engraven record of the complex sound-waves set in motion by these performances, and you know that when the wax tablet or cylinder is placed in a suitable machine these sound-waves can be repeated and the original music reproduced. In the same way, when I show you a small roll of kinematograph film bearing, say, 5000 little photographs, these photographs having *no trace of colour* about them, you are to understand that they carry within themselves, in their long range of tones and half-tones so to speak, a record of the colour-waves received by the lens when the picture was taken, and when this film is run through a bioscope projector fitted with the proper attachment the recorded "colour-waves" are again set in motion and the scene is reproduced to our eyes in its proper colours.

The principle, as we understand it, is as follows. First of all, a film is used which is rendered as sensitive to red, yellow, or green rays as the ordinary photographic film is to blue rays. This is run through a kinematograph camera in the usual way, with the exception that between the film and the lens is a rotating disc part of an annulus which is composed of a green gelatin screen—i.e., blue plus yellow—and another part of the same annulus of an orange red screen—i.e., red plus yellow. The film when developed shows no colour at all but only the ordinary gradations of black and white. When, however, this film is again run through the kinematograph lantern, with the revolving disc between it and the lens, the colour waves are again actuated and the photographs on the film appear upon the screen in colour. The demonstration referred to, though Mr. Smith impressed upon his audience that the invention was yet in an experimental and incheate stage, was of extreme interest. Thus, the photograph of a lady in a white dress with red sash and red roses in her hat came out in very pure colouring, while another photograph of a child dressed mainly in green who held up at intervals a tartan plaid, the tartan containing a great deal of red and yellow, came out equally well. Allowance has to be made for the fact that as the films were taken by daylight and exhibited by the arc light the colours naturally showed some slight deviation from the appearance which they would have presented by daylight. So far as we can see the invention has a promising future before it. It does not appear, however, that it will be of any more value in medicine for the representation of colour changes in disease such as various affections of the skin, pigmentations and the like, than the Lumière process, for, of course, the question of motion does not enter into such cases.

PERFORATION OF THE GALL-BLADDER IN ENTERIC FEVER.

ALTHOUGH inflammation of the gall-bladder frequently occurs in enteric fever and many cases of post-typhoid cholecystitis have been reported an operation for perforation of the gall-bladder during the disease is a great rarity. In the *American Journal of the Medical Sciences* for April Dr. A. P. C. Ashhurst has recorded two cases. In the first case a boy, aged 12 years, was admitted into hospital about the end of the third week of an attack of enteric fever. The temperature was 101·8° F., there were rose spots and enlarged spleen, and Widal's reaction was positive. He became delirious and the temperature ranged from 103° to 104° and the pulse from 120 to 130. On the thirty-second day of the disease at 10 A.M. he complained of pain in the right side of the abdomen and there was some rigidity of the right rectus muscle, and the most tender *spot* in the abdomen was over this muscle at the level of the umbilicus. At 11 A.M. the pain, tenderness, and rigidity had considerably increased and the abdomen moved very little with respiration. At 1 P.M. the symptoms had further increased, the abdomen was distended, and tenderness was no longer localised but had spread over the whole abdomen, remaining, however, greatest on the right side. There had been practically no change in the pulse-rate but within three or four hours the temperature had fallen from 104·4° to 102·4° and the leucocytes from 10,200 to 6200. Intestinal perforation was diagnosed. At 3 P.M., under ether, a transverse incision was made in the right iliac region. Much bile-stained fluid was found on sponges inserted among the intestines. The whole of the small intestine and about six inches of the ascending colon were examined but no perforation was found. All the intestines were much congested and inflamed. On account of the patient's critical condition no further attempt was made to find the cause of the peritonitis. A tube was introduced and the wound was partly closed. Death occurred 20 hours after the operation. The necropsy showed general peritonitis and perforation of the gall-bladder. In the second case a youth, aged 20 years, was admitted into hospital at the end of the second week of an attack of enteric fever. The temperature was 104° and the pulse was 120. The spleen was slightly enlarged, there were a few rose spots, the Widal reaction was positive, and the leucocytes numbered 8000. About the thirty-seventh day of the disease the temperature became normal but on the thirty-ninth and fortieth day it rose irregularly. On the forty-first day at 8 A.M. the temperature rose to 104° and the pulse to 120. The patient vomited greenish fluid and complained of not feeling so well as previously. He had no pain but on deep palpation below the right costal border slight but distinct tenderness was found. His general condition was good and the leucocytes numbered 24,000. Calomel and magnesium sulphate were given but were vomited. On the following day at 4 A.M. the temperature was 100·2°, the pulse was 136, and there were severe pain and tenderness in the right upper abdominal quadrant. The right half of the abdomen was very rigid. There was no distension or dulness in the flanks. The resident physician diagnosed perforation of the gall-bladder. Dr. Ashhurst was summoned and was surprised to find that the patient looked like a man of 40. His expression was characteristic; there was not the Hippocratic facies but a general weakening of all the features. At 8 A.M., four hours after perforation, a small incision was made through the outer border of the right rectus muscle above the level of the umbilicus. There was a little serum in the peritoneal cavity. The transverse colon was found adherent to the liver and the incision was extended upwards for a distance of four inches. The upper abdominal region was isolated by gauze packs and slight recent adhesions were cautiously ruptured. Serous fluid welled up from above the transverse colon and was followed by four ounces of thick inodorous pus which seemed to come from the under surface of the liver. The gall-bladder was buried in dense adhesions between the liver and colon and showed a ragged perforation measuring 1¼ by 1½ inches. The gall-bladder was excised and its neck was ligatured with chromic catgut. A drainage-tube was inserted and the incision was partly closed. Recovery was almost uneventful. The pus yielded the typhoid bacillus in pure culture. Dr. Ashhurst has found records of 19 operations performed on the gall-bladder during enteric fever. These include aspiration of the gall-bladder through the abdominal wall, cholecystendysis, cholecystotomy and drainage, cholelithotomy, and cholecystectomy. Adding Dr. Ashhurst's two cases, recovery took place in eight out of 21 cases.

THE TREATMENT OF SINUSES WITH BISMUTH PASTE.

IN the *Journal of the American Medical Association* of March 14th Dr. E. G. Beck has described a new method of treating sinuses and chronic abscesses from which he has obtained good results. It is well known that bismuth offers great resistance to the passage of the x rays. Dr. Beck injects into sinuses a paste made with one part of bismuth and two parts of vaseline and takes a radiograph. The shadow shows the shape of the cavity and its ramifications. Sometimes the result is most surprising and shows that patients have not been cured after several operations because all the tract of the sinus has not been removed. A subsequent operation done under the guidance of the radiograph has proved successful. Moreover, the bismuth paste has also curative properties. After one injection a psoas abscess which had existed for nearly two years permanently closed. A girl, aged four years, had a sinus resulting from a psoas abscess which had discharged pus for nearly two years. Bismuth was injected and the skiagraph showed that the fistula extended from Scarpa's triangle along the psoas muscle to the junction of the second and third lumbar vertebræ, where the bismuth filled a space about three-quarters of an inch long and one and a quarter inches wide. A few days later the sinus stopped discharging and two months later it had closed permanently. Another skiagraph was taken and it was found that the bismuth had all disappeared. The method of injection is as follows. The sinus is first dried by packing it with a strip of gauze half an inch wide which is removed just before injection. The paste is sterilised and while hot and liquid a glass syringe is loaded with it. The tip is tightly pressed against the opening of the sinus and the paste is forced in very slowly until the patient begins to complain of pressure. The syringe is then removed and a small gauze sponge is quickly pressed against the opening to prevent the escape of the paste before it has hardened. An ice bag may be applied to hasten the hardening. The injections are continued until the discharge ceases and then a harder preparation containing 5 per cent. of soft paraffin and 5 per cent. of white wax is used, after which the fistula usually remains closed. This treatment is applicable to all sinuses, fistulas, and abscess cavities except intracranial sinuses and biliary and urinary fistulas.

A CONVERSAZIONE will be held at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., on Monday, May 18th. The President will receive the company at 8.30 P.M. and subsequently he will present the Fothergillian medal to Sir Almroth Wright, F.R.S. At 9 o'clock Mr. Clinton T. Dent will deliver an oration on the After Results of Injuries.

A COURSE of eight lectures on Some Aspects of the Physiology of the Heart and Circulation, by Mr. Leonard E. Hill, M.B., F.R.S., and Mr. Martin Flack, B.A., will be given in the physiological theatre of the London Hospital on Tuesdays, at 4.30 P.M., beginning on May 12th. These lectures, are free to all students of the University of London.

Professor David W. Finlay, M.D. Glasg., LL.D., F.R.C.P. Lond., will preside at a dinner of the Glasgow University Club, London, at the Trocadéro, Piccadilly-circus, London, W., on Friday, May 29th. Applications for tickets should be addressed to the honorary secretaries.

THE Governor of Hong-Kong in a despatch to the Secretary of State for the Colonies states that 39 cases of plague were reported during the week ending May 2nd, the number of deaths being 39.

INTERNATIONAL FIRST AID CONGRESS. — The forthcoming congress at Frankfort-on-the-Main, which is to be held during Whitsun week (June 9th to 13th), promises to be a great success. Registrations, in order to participate in the proceedings at the congress, are being received daily, and it is confidently believed that in point of numbers the attendance will far exceed 700, the number at first estimated. The honorary committee is composed of influential and distinguished members and includes the German Imperial Chancellor (Prince Bülow) and representatives of the departments of state of the German Union of States. A committee meeting of the British section was held on April 29th at which the Duke of Marlborough, K.G. (who has stated his intention of being present at Frankfort), presided. It is reported that great and increasing interest was being evinced in the project and it was further stated that Great Britain, which always takes the keenest interest in such matters as the congress is being held to discuss, will be well represented. We have been asked to state that any person interested in the cause and who is desirous of becoming a member should at once communicate with the honorary secretary, Mr. S. Osborn, F.R.C.S., Datchet, near Windsor, as time is now very short.

REPORT OF THE BELFAST HEALTH COMMISSION.

THE report of the Belfast Health Commission is a document of great interest and is a storehouse of valuable information on the subject with which it deals. The citizens of Belfast who demanded the inquiry did so on two grounds: first, because they believed, founding their comparison on the statistics supplied by the Irish Registrar-General, that the death-rate of the city of Belfast when compared with that of the majority of the larger cities of the United Kingdom was excessive; and secondly, that the excess was caused largely by diseases of the classes which in the present state of sanitary science are known to be preventable. The Commissioners in their conclusions find that the death-rate from all causes in Belfast is, and has been for several years, about the same as that of Manchester, rather lower than that of Dublin or Liverpool, but not so low as that of other large cities of the United Kingdom, and they say that "although the death-rate of Belfast *from all causes* is by no means low, we think the allegation that it is, or has been in recent years, excessive cannot be maintained." Their verdict on this question is arrived at by estimating the population of the city of Belfast for 1906 as about 380,000 instead of 366,220 as given by the Irish Registrar-General. Everyone admits the difficulty of calculating the population of growing cities in intercensal years (Sir Robert E. Matheson's method is to arrive at the results by a consideration of the birth-rate, of the effects of emigration and immigration, and of any local facts of which he is able to obtain knowledge, while the Commissioners' calculations are based on the birth-rate), and as it will only be known for certain at the next census in 1911 what the population is, the estimate of the Commissioners can after all only be regarded as problematical. It is well known that Belfast has not been increasing of late years as it did, and it is just as probable that the estimate of the Irish Registrar-General may in the end turn out correct, which would as a result make the death-rate higher than it is estimated according to the Commissioners' calculations.

But, even accepting the Commissioners' results, is it any ground for satisfaction that a new, beautifully situated, and quite modern city like Belfast is only exceeded in its general mortality, taking large cities, by Dublin (which has so long enjoyed a very unenviable position for its high death-rate) and by the densely populated city of Liverpool, which from its being the great port of the Empire is constantly exposed to influences not present to the same extent in any other British city? As to the second point—that is, the excess of deaths in Belfast caused by preventable disease—the conclusions of the Commissioners are very striking, for in reference to enteric fever they say that the mortality from it in Belfast has been excessive in almost every year since the time (1872) when deaths from this disease were first separately recorded in the returns of the Registrar-General of Ireland. For the last 25 years at least the mean annual mortality from this disease has been so great in Belfast that no other city or town (the Commissioners say) of the United Kingdom equals or even approaches it in this respect. Indeed, the very excess of this disease has been so great as to "make Belfast unique in this respect among communities in the United Kingdom." Then as to pulmonary and other forms of tuberculosis, the mortality has been, and is, excessive in Belfast (the Commissioners report) in comparison with English and Scottish cities, but it has not been exceptional for an Irish city.

As to infantile mortality, Belfast holds a not unfavourable place in comparison with other great cities in the United Kingdom (146 per 1000 births in 1901-05), due largely to the fact that the nursing of infants by their mothers is more extensively and more thoroughly carried out in Belfast than in either England or Wales. The Commissioners think that it is probable that the rate of infantile mortality in Belfast is somewhat understated, but even taking it as calculated they say "it is not to be understood that the Belfast rate of infantile mortality is low, or as low as it might be. Steps should be taken to continue examination of the causes of death among infants and as a result to devise further means of reducing this mortality." Moreover, the Commissioners point out that influences seem to exist in Belfast of a sort to cause undue mortality among all young people, but especially so among females between the ages of five and 45 years—that is to say, among females during a period of life which embraces the school age, the age of puberty, the young working age, and also the child-bearing age. They commend the detailed analysis of these mortality returns to the Belfast corporation.

In reference to the prevalence of enteric fever, in the *opinion of the Commissioners insanitary conditions have no* doubt played a very important part in fostering enteric fever in Belfast but cannot of themselves account for so excessive a mortality from this disease or for other features of its history, nor do they think that the water-supply can account for enteric fever in Belfast, because there has been no relation between the distribution of the disease and the distribution of any one of the three separate sources of water-supply. On the contrary, the incidence of enteric fever in different parts of the city has been generally similar and simultaneous, irrespectively of water-supply or insanitary conditions, and, moreover, it appears to have almost exclusively affected the working-class areas of the city. The prevalence of enteric fever in Belfast, the Commissioners think, is due to the influence, direct and indirect, of shell-fish gathered from the grossly contaminated foreshores of Belfast Lough. An extremely valuable addendum to the report on "Enteric or Typhoid Fever in Belfast," by Dr. L. W. Darra Mair, is in support of the same view and should be read by everyone interested in the etiology of enteric fever. On the other hand, some will think that the case for the shell-fish origin is hardly proved and that the extraordinary and continued prevalence of a disease like enteric fever (in 1898 two out of every 1000 of the population in Belfast died from enteric fever) *suggests* a much more widely diffused and constantly acting cause than the eating of raw shell-fish. It may be pointed out that a careful inquiry made some time ago at the Fever Hospital in Belfast disclosed the fact that the consumption of raw shell-fish by those who suffered from enteric fever was an infinitesimal factor in the cases.

It is to be regretted that in reference to the "white plague of Ireland"—tuberculosis—the Commissioners seem to have failed to face the question and this is the more remarkable because it was largely on account of the prevalence of tuberculosis that the Commission was appointed. Two questions were raised at the Commission: the great prevalence of pulmonary tuberculosis in Belfast and in Ireland, and all we can gather from the report is that "the age and sex incidence of phthisis mortality in Belfast and Ireland is very different from what it is in Manchester and in England and Wales. It may, to some extent, be due to differences in disease nomenclature in the two countries. The whole question of phthisis in Ireland seems to us to require further and exhaustive inquiry. We have refrained from any recommendations in regard to the notification of phthisis and the provision of sanatoria or dispensaries, as the Local Government Board for Ireland have advised local authorities in recent years, and we understand that a Bill on these subjects is about to be introduced by the Chief Secretary for Ireland." Since 1864 the mortality from tuberculosis has steadily fallen in England and Scotland while it has as steadily risen in Ireland. Surely a commission (on which both English and Scotch public health experts sat) should have tried to give the people of Ireland some explanation of such a deplorable state of affairs and how it could be prevented. This is undoubtedly the weakest and most disappointing part of the whole report.

The report is a vindication of the action of the medical profession who urged, when the position of medical officer of health was last vacant, that a man of thorough practical experience and training in public health should be appointed at an adequate salary, and that he should be sole head of his department. "In view," the Commissioners say, "of the many complaints which for several years had arisen in connexion with the work of the Public Health Department, it was of primary importance that a man of wide experience in public health administration in other places should have been appointed, and that a salary should have been offered which would have attracted highly qualified and experienced candidates. This view was very strongly urged upon the corporation by the Local Government Board but was not adopted. We consider that a grave mistake was made by the corporation in not accepting this advice. *This office*, for a city like Belfast, is always of great importance, and was especially so in the circumstances of the moment; and it must be remembered that the issues at stake concerned the health of a large industrial city, eighth in population in the United Kingdom. Unfortunately, in Belfast it has been customary to fill this position by electing a former member of the corporation thereto, and it is obvious that when a comparatively low initial rate of salary is proposed, and it appears probable that local connexions will outweigh special qualifications for the discharge of the duties of the office, the choice of candidates is likely to be restricted."

The Commissioners are totally opposed to the present arrangement by which there are 14 local medical officers of health (dispensary doctors) appointed by the guardians, while the medical officer of health is elected by the corporation, and they report that this system should be abandoned as unsuitable and unworkable in the case of a large city like Belfast, and that instead reorganisation should be effected so as to bring the public health administration into line with that which obtains in the great cities of England and Wales and Scotland by making provision for the appointment of a special medical staff for public health work. The whole responsibility of the administration would thus be placed on the central medical officer of health who should have such assistance as may be deemed necessary. The Commissioners are very severe on the present system in Belfast by which the chief medical officer of health is not supplied with vital statistics which the late Dr. Farr said formed the basis of all health reform. "The cause of not one infant's death in Belfast is known to the Belfast corporation. Similarly the causes of death among children are quite unknown, or indeed the causes of death among persons of whatever age. Likewise the corporation are completely in the dark as to places where deaths in the city are occurring even from such important diseases as phthisis, tuberculosis, pneumonia, cancer, diarrhœa, or from diseases which may be due to industrial causes, to poverty, or to any of the other conditions which may be thought of as associated with modern town influences. And even in regard to the principal epidemic diseases similar ignorance prevails, except in regard to those which are notifiable under the Infectious Disease (Notification) Act." Further, the Commissioners say "it it therefore impossible for Belfast to institute what may be termed a 'pathological register' in which to record the sex, age, residence, and nationality of every diseased person, the size, situation, sanitary circumstances of his house, and so on, such as has proved of great value to other local authorities." They wisely say that it is obvious that the matter cannot be allowed to rest thus and that the most effective and most natural method of dealing with it is to follow the precedent of the English and Scottish Registration Acts, even if such a method involves fresh legislation, and they strongly recommend that this should be done without loss of time.

The report may be described as containing a series of admirable recommendations, to some of which we have already alluded. In reference to the water-supply a more thorough filtration is advised, and the early development of the Mourne supply is considered to be the main feature of future policy; and further, it is recommended that the water-supply should be in the hands of the corporation. Capital advice is given as to sewage disposal, sanitary administration (including the appointment of a special medical staff for public health work, the appointment of a bacteriologist, increase of sanitary sub-officers, increased accommodation for infectious cases, the provision by the corporation of an efficient steam disinfecting apparatus, the removal of refuse, and the proper treatment of insanitary areas), milk- and meat-supplies, schools, and conditions of employment. But the impression left by a perusal of the report can hardly fail to be that in the great city of Belfast, the most populous city in Ireland and the eighth in the United Kingdom in regard to population, the science of public health is in a more backward condition than in any town of its size in the United Kingdom. The report is, as we have already pointed out, a thorough vindication of the action of those who, in the interest of the health of their city, asked for the appointment of such a Commission. It is hoped that a further step will shortly be taken—namely, to urge the Irish Government authorities to demand that the weighty suggestions in the report shall be carried out and that they shall not be "pigeon-holed" as those of the "Harrison" Committee were in 1896—a report of great importance, because, as the present Commissioners say, "it expressed the views of a committee of the corporation on their own administrative methods."

Those of the public health committee of Belfast who think because the Commissioners estimate the population of Belfast as higher than the careful calculation of the recognised authority—the Irish Registrar-General (who will be entitled to criticise their figures)—that they have gained a victory over those who asked for the appointment of the Commission, must be compelled to face the very serious and numerous recommendations contained in the report. It is interesting to note that the Local Government Board has written to the corporation of the city of Belfast urging it to "bestow upon the report and the valuable recommendations therein contained that immediate and earnest consideration which a matter so seriously affecting the health of their city demands."

THE REMOVAL OF KING'S COLLEGE HOSPITAL TO DENMARK HILL: MEETING OF SOUTH LONDON MEDICAL PRACTITIONERS.

ON April 30th a largely attended meeting of general practitioners of South London was held at the Camberwell town hall to consider the future administration of King's College Hospital as it will affect the practitioners of South London, the district into which it is to be removed. Very nearly 100 attended the meeting which was held under the auspices of the South London Hospitals Committee, the chairman of which body, Mr. Robert Capes, occupied the chair. Before opening the business of the meeting the chairman proposed a vote of sympathy with the widow and relatives of the late Mr. C. H. Brangwyn, a member of the committee, which was passed in respectful silence. He then proceeded to explain that the South London Hospitals Committee had been created to confer on behalf of the medical practitioners of that district with the Watching Committee of King's College Hospital, a body appointed by the board of the Medical School with advisory but not executive powers as to the administration of the new buildings. He expressed gratitude for the very reasonable and fair attitude which the hospital had adopted towards the practitioners of South London, and insisted that there was no question of their opposing the advent of the hospital and that it was desirable to work in harmony with the Watching Committee. A year ago the two committees held a conference at which the practitioners presented to the watching committee 17 resolutions designed to check abuse of the hospital charity and to safeguard the interests of neighbouring medical men. Of these the watching committee agreed to the following 15 (although it would appear that Nos. 7 to 10 depend on No. 6 which was not approved) :—

1. That there be no issue of subscribers' letters.
2. That sickness and poverty be the qualifications for hospital treatment.
3. That no charge be made for the treatment of any patient of the hospital, or for the supply of medicine or dressings.
4. That urgent cases receive attention without inquiry.
5. That each applicant for treatment, on the first visit, be seen by a registered medical practitioner and if found suitable for hospital treatment attended to; and that the name, age, address, occupation, or position be entered in a register.
7. That such certificate be written on a form supplied by the hospital.
8. That such certificate, duly filled up, be appended to each patient's prescription-paper or attendance-card.
9. That the following be submitted to the authorities of King's College Hospital as the ordinary form to be supplied to patients attending the hospital for the first time.

MEDICAL CERTIFICATE.

I hereby recommend.............................. aged ....
as a suitable case for treatment at the.........................Hospital.
....Registered Practitioner.
.............................19.........
No charge is made for this certificate.

(REVERSE SIDE OF CERTIFICATE.)

In signing this certificate, the practitioner is requested to keep in view two points:—
(1) That the applicant is not in a position to pay for treatment;
(2) That the case is, from a hospital point of view, suitable for treatment.

10. That a similar certificate be required in maternity cases.
11. That it would be satisfactory if a system could be arranged whereby obscure and interesting cases might be brought or sent with a note by practitioners for an opinion when a consultation fee cannot be paid.
12. That all cases of trivial accident or illness deemed ineligible for the out-patient department shall, after having been once attended to, be referred for treatment elsewhere.
13. That, should a general practitioner report in writing the attendance of a person well able to pay, the letter if duly signed be treated as confidential and the matter investigated.
14. That the hospital authorities use every means in their power to prevent unsuitable cases receiving hospital treatment, and appoint such officers as they consider desirable to make inquiries with a view to checking hospital abuse.
15. That the regulations as to the admission of patients for treatment be displayed in conspicuous positions in the hospital.
16. That no patients except maternity cases be attended outside the hospital.

The two following resolutions were not approved by the watching committtee :—

6. That, on a second application for treatment, a patient bring with him a recommendation signed by a qualified medical practitioner stating that such patient is a suitable person for hospital treatment.
17. That private wards or nursing homes for paying patients be distinct from the general hospital and not erected or maintained out of the funds given for hospital purposes.

It was to discuss these important points of principle that the meeting was convened.

Dr. M. G. **BIGGS** proposed the following motion :—

> That this meeting strongly disapproves of paying patients being admitted into general teaching hospitals erected out of charitable funds, and sincerely hopes the authorities of King's College Hospital will not adopt any system for the admission of paying patients.

He endorsed fully the chairman's remarks concerning the considerate and courteous treatment shown by the Watching Committee to the South London practitioners. He explained that the hospital only intended to take in *contributory* patients to the paying beds—i.e., to charge them only for maintenance and not for treatment, as it was thought there was need of accommodation for such people as were above the general run of hospital patients but relatively worse off than that class. They were to be admitted to special wards and used for teaching purposes and to be treated by the hospital staff. The British Medical Association had laid it down that there was no objection to paying wards in hospitals if they were open to the general body of practitioners to send in cases which they could themselves continue to treat. Dr. Biggs went on to speak of the temptation experienced by hospitals having paying wards to exploit them as a means of gain and submitted that it was neither wise nor right to use charitable funds for investment in such commercial undertakings. "Contributory" patients could be cared for equally well by their own medical attendants in special nursing homes or cottage hospitals managed by committees on which medical practitioners should be properly represented; to such hospitals younger consultants would gladly come for moderate fees if required for purposes of consultation or to carry out special treatment.

Dr. J. F. W. **SILK**, secretary of the King's College Hospital Watching Committee, said it would be four years before patients could be admitted to the new buildings, so the matter was not urgent. All over the country lay people were bringing pressure to bear upon hospitals to institute paying beds, and the present scheme had been put forward in deference to such pressure. He submitted that the public paying the piper had a right to call the tune. The Watching Committee held that it was utterly impracticable to throw the wards of a teaching hospital open for all or any local practitioners to have charge of cases treated in its wards. Every possible precaution would be taken to prevent abuse of the contributory beds, which would be in annexes to the general wards; each was to hold two beds, a number considerably less than had been originally proposed, thanks to the Watching Committee's strong representations. The almoner would be able to check any abuse of these beds. In answer to Dr. F. G. Swayne Dr. Silk stated positively that the contributory beds would not be made a matter of gain to the hospital.

Dr. J. H. **KEAY** also spoke to the motion which was put to the meeting after the proposer had replied and was carried unanimously.

Dr. R. **ESLER** then moved :—

> That it is the opinion of this meeting that the system of admission to King's College Hospital by certificates from the medical practitioners as set forth in resolution 6 of the South London Hospitals Committee should be given a fair trial, and this meeting strongly urges the authorities of King's College Hospital to incorporate this system into the rules of the hospital.

He acknowledged that the system would entail much trouble to practitioners but declared that their interest in the matter was apparent. Hospital abuse was not the fault of the members of hospital staffs, although they were often blamed by general practitioners for treating patients who could afford to pay. This proposal gave a solution to the difficulty.

All great hospitals were in need of funds and treated too many out-patients. Medical men could get more influence on hospital committees if they would stand firm. In the course of his speech Dr. Esler made certain remarks concerning feminine competition which, considering the presence of lady practitioners in his audience, might have been omitted.

Dr. E. R. FOTHERGILL moved the following amendment:—

1. That this meeting of South London registered medical practitioners understanding (1) that at the present time a Royal Commission is inquiring into the Poor-law system; (2) that the King Edward Fund has decided to inquire into the system prevailing at the large general hospitals of London with regard to the admission of out-patients; and (3) that for the uses of the sick poor resident in Camberwell and district there are already provided 25 hospitals, five infirmaries, 18 dispensaries, and nine other institutions, considers that there has been no evidence offered of the necessity for any out-patient department at the proposed King's College Hospital on the lines of those at the large London general hospitals; regrets that a contract for £55,000 for such a department has been placed; and is of opinion that a small out-patient department to which will be admitted either for consultation or treatment only those recommended as suitable by registered medical practitioners, as suggested in Resolutions, 6, 7, 8, 9, and 11, would amply meet the needs of the district, would fulfil all requirements for the education of students, and should be given a fair trial.

2. That the Lambeth, Norwood, and Wandsworth divisions, the Metropolitan and South-Eastern Branch Councils, as well as the Central Council and Representative Body of the Association, be urged to approve and support this resolution, a copy of which shall also be sent to King Edward's Hospital Fund, the Hospital Saturday and Sunday Funds, the Charity Organisation Society, King's College Hospital Board, THE LANCET, the *British Medical Journal*, and the press generally.

His speech was a well-considered and able elaboration of the arguments embodied in the amendment. He insisted that the interests of the profession and the public coincided, deplored the fact that hospital rivalry had led to commercial exploitation of the statistics of patients treated, instancing a recent increase of 100,000 per annum of out-patient attendances at Guy's Hospital with a consequent loss to the general practitioner. He submitted that South London did not want an out-patient department for King's College Hospital which should coöperate with existing dispensaries. There were five classes of hospital out-patients: (1) those who could afford to pay for advice; (2) those who were in clubs and dispensaries but yet went to hospital; (3) those who ought to be in, but would not join, clubs and dispensaries; (4) Poor-law cases; and (5) cases genuinely needing a second opinion and unable to afford a consultant's fee. A *consultation* department would be legitimate and useful—in fact, more useful for teaching purposes than the present out-patient departments. The speaker drew a striking picture of the present unsatisfactory method of dealing with out-patients at general hospitals from the point of view of the patients, the students, and the medical staff in charge. Over 150 medical men in the neighbourhood had promised to give the scheme a fair trial. Dr. Fothergill finished his remarks with a spirited appeal to the older practitioners to assist the younger in their struggle.

Dr. L. S. McMANUS, after congratulating the meeting on showing so united a front against a common enemy, gave a clear account of the system in practice at the Bolingbroke Hospital, of the staff of which he is a member. The special departments of the hospital were each in charge of a London consultant of high standing who attended on special days. Each out-patient brought up a card from his own medical attendant and the consultant wrote his opinion on a form which was sent back to that practitioner who carried out the treatment himself. He insisted that this was a more rational and honest method than that of giving the patient a quart of medicine at the hospital and telling him to come back in a fortnight, no matter what happened to him meanwhile. Dr. McManus enlarged upon these arguments in forcible and telling manner.

The amendment was debated by Mr. C. W. HOGARTH, Dr. KEAY, and Mr. V. S. PARTRIDGE with regard to the feasibility of the medical certificate system; the possibility of certain abuses was suggested.

Mr. H. HARVEY NORTON said that such a card system had failed hopelessly at the Belgrave Hospital and he suggested that local practitioners should subscribe to support their own almoner at the hospital.

Dr. SILK protested that it was too late to object to an out-patient department which had already been planned by King's College Hospital.

Dr. FOTHERGILL again pleaded that his plan should be given a fair trial, and the amendment was put to the meeting and carried by 58 votes to 9, and passed again without further discussion as a substantive motion.

Mr. W. SOPER moved a vote of confidence in the South London Hospitals Committee, which was carried unanimously, as were votes of thanks to the Chairman, to Dr. Silk for his attendance, and to the mayor and town council of Camberwell for the use of the town hall for the meeting.

THE ROYAL ACADEMY.

THE 140th exhibition of the Royal Academy of Arts was opened to the public on May 4th, and the protagonist of the exhibition is undoubtedly Mr. Charles Sims, to whose pictures we shall refer later. To begin with the pictures having a medical interest, Mr. J. Seymour Lucas shows a portrait of Sir Francis Laking (348) in gorgeous robes and decorations, while Mr. John Collier (428) exhibits a work called "Sentence of Death," which we imagine represents a physician telling a patient that he is doomed. We presume that he is a physician because on his desk are a microscope, a stethoscope, and a sphygmomanometer. The nature of the patient's illness is by no means easy to diagnose. He is quite young, he is evidently not suffering from advanced tubercle, he is not bronzed enough for Addison's disease, so we can only suggest visceral sarcoma. A work which may well be compared with this is Mr. Edgar Bundy's dramatic rendering of an episode during the Great Rebellion called "The Sands of Life" (324), in which a captured cavalier sits waiting for death whilst the sands of an hour-glass are running; among the Puritans who stand watching him is a fanatical preacher of the type that used to be called by the Cavaliers "a Doddipot and a Green-headed Trumpeter"; it must be some consolation to the unfortunate prisoner that when the sands have run out the exhortation will come to an end. The work is very strong in the various expressions of the different faces, on some of which a firelight plays. Turning to Room 1, Mr. George Clausen's "Gleaners Returning" (4) will at once attract attention, while No. 14, Mr. Mouat Loudan's "The Crystal," which has been most unjustifiably skied, is singularly charming. Mr. J. J. Shannon's "Princess Patricia of Connaught" (16) is in every way worthy of being placed by the side of the magnificent portraits of her father and mother by Mr. Sargent, which are in Room No. 3. Another portrait in this room merits attention—namely (23), by Sir W. Q. Orchardson, the subject being Nurse Charles (Mrs. W. H. Wood)—but the gem of this room, in fact, we think we may say of the whole collection, is (50), Mr. Charles Sims's "The Little Faun," a truly exquisite fantasy, full of the spirit of Theocritus. Mr. Sims has the true child spirit, such as Thomas Traherne wrote of when he said,

> "Then did I dwell within a world of light,
> Distinct and separate from all men's sight,
> Where I did feel strange thoughts, and such things see
> That were, or seemed, only revealed to me."

No. 55, "A Ligurian Garden," shows Mr. La Thangue in his sunniest mood. In Room 2 Mr. Shannon exhibits an experiment in the nude called "The Infant Bacchus," in which it would almost appear as if one nymph had been painted from a model who has been in the habit of tight-lacing. In Gallery No. 3 besides Mr. Sargent's *portrait*, which we have already noticed, Sir Hubert von Herkomer has a strongly painted portrait of the Bishop of London (183), next to which Mr. David Murray has a wonderful study of sea and sky, which would seem to be a recollection of the amazing Krakatoa sunsets of 1884. Mr. George Clausen in (202) shows one of his vigorous and spiritual studies entitled "The Boy and the Man." In (207) Mr. Sargent has a striking portrait of Mr. A. J. Balfour. In (239) Mr. J. M. Swan shows his usual skill in portrayal of pumas and jaguars in his presentment of Saint Maldonada, who, be it remembered, was tied up to a stake for the wild beasts to eat and who was guarded from destruction by pumas. In Gallery No. 4 Mr. Frank Brangwyn exhibits (257) a magnificent piece of decorative colour-work called "The Return." It is a decoration which ought to be bought by some millionaire who possesses a gallery like that in Carabas Castle immortalised by Thackeray in the "Book of Snobs," which the housekeeper described as "One 'undred and forty-eight in lenth by thirty-two in breath," for it requires to be seen at a distance of about 40 feet to be appreciated properly. Mr. Frank Bramley's portrait group, "Helen Graham Chalmers and Her Mother" (300), is full of light and air and colour. In Gallery No. 5 Mr. C. W. Wyllie's (347), also called "The Return," is worthy of close study and comparison with Mr. Brangwyn's treatment of a similar idea; and Mr. Sims in (361) has, we are glad to say, captured the Chantrey Fund by "The Fountain," a study of falling waters, light, and nymphs, which shows the artist in the best sense to be truly *νυμφόληπτος* Our space is too limited to allow us to do more than mention a few of the remaining pictures. In (417) Mr. George Henry has a charming portrait study which he calls "Silk and Ermine," and another striking portrait is (433), H.H. the Maharajah Orocha, by Mr. Herbert Olivier. Mr. George Harcourt (480) exhibits a brilliant piece of work entitled "Supper in Summer Time." In the room popularly known as the "Gem Room" Miss C. M. Wood has a very clever study of the splendid colours shown by various copper ores (683). Two adjoining pictures in Gallery No. 10 should on no account be missed, these being Nos. (877) and (878), by Mr. Raven Hill and Mr. G. Sherwood Hunter respectively, the former being a study of a lady seated in subdued light at a piano, and the other a Brittany "First Communion" with a charming effect of light from a hundred candles mixing with the daylight. Mr. E. A. Hornel in (897) has a picture singularly reminiscent of his exhibit in the New Gallery, and in (975) Mr. W. W. Ouless shows a good portrait of Mr. Pridgin Teale. Of the water-colours we have only space to notice the President's little picture of Amat Forest, Ross-shire.

Of the sculpture we must first mention (1848) Mr. Herbert Frampton's bust of Dr. J. Hughlings Jackson, which is to be placed in the Hospital for Epilepsy and Paralysis, Queen-square, Bloomsbury, London, W.C. Mr. F. Lynn Jenkins' group (1851), "The Ides of March," shows well the lifelessness of Cæsar's body as opposed to the two senators straining to support it. Other notable statues are (1820) Mr. Harold Parker's "Ariadne" and (1974) Mr. Bertram Mackennal's "Diana," two beautiful nudes which have been acquired for the nation by the Chantrey Fund, which has also rightly acquired Mr. C. L. Hartwell's vigorous little bronze of elephants which he calls "A Foul in the Giants' Race." Lastly, we must mention (1973) Mr. Goscombe John's model of altar tomb and effigy of the late Marquis of Salisbury, and (1976) Mr. F. Derwent Wood's "Psyche." On the whole we consider that this year's Academy exhibition is one of the most interesting of those which have been held during recent years.

BRITISH MEDICAL BENEVOLENT FUND.

AT the April meeting of the committee 20 cases were considered and grants amounting to £202 were made to 18 of the applicants, two cases being postponed for further inquiry. Three vacancies for annuitants of £20 were filled by selected candidates. Appended is an abstract of the cases relieved:—

Daughters, aged 54 and 47 years, of late M.R.C.S. Since loss of means some years ago through the dishonesty of a trustee applicants have supported themselves by acting as companions, &c., but just at present have no engagements. Voted £10.

L.R.C.P., L.R.C.S. Edin., aged 48 years. Had one eye enucleated 12 years ago and has since lost sight in the other. No income. Wife lets lodgings. Five children, aged 13 to eight years. Voted £18.

Four children, the eldest 13 years and the youngest one month, who have lost both parents during the current year. Are given a home by maternal grandfather, a clergyman with small means and a large family. Voted £10, with leave to apply again in six months.

Daughter, aged 65 years, of late M.D. Lond. Only income £4 a year from savings during 40 years of teaching. Now endeavours to support herself by knitting and needlework. Voted £12.

Daughter, aged 57 years, of late L.S.A. Lets lodgings and has to support a sister incapacitated by ill-health. Voted £12

Daughter, aged 31 years, of late L.R.C.P., L.R.C.S. Edin. Has maintained herself as a nurse-companion but is now incapacitated by rheumatoid arthritis. No income. Voted £10.

Widow, aged 57 years, of M.D. Edin. Has a post as housekeeper but at present has to support a daughter who is temporarily incapacitated. Voted £5.

Widow, aged 60 years, of M.R.C.S. No income. Children unable to help and health very bad. Relieved twice, £24. Voted £12.

Widow, aged 45 years, of L.R.C.P., L.R.C.S. Edin. No income. Health very indifferent. Two sons who are sailors only just self-supporting. Relieved four times, £39. Voted £12.

Daughter, aged 58 years, of late M.R.C.S., who was an annuitant of this Fund. Is given a home in exchange for services as working housekeeper, but receives no salary. Relieved seven times, £108. Voted £10.

Daughter, aged 58 years, of late M.D. Aberd. Endeavours to support herself by teaching music, but finds increasing difficulty in obtaining pupils. Relieved once, £10. Voted £10.

Widow, aged 53 years, of M.B. Aberd., whose means were exhausted by a long illness which preceded his death. For some time past applicant has held a post as nurse-companion but has been obliged to give it up on account of ill-health and at present is incapacitated. Children just self-supporting. Relieved once, £5. Voted £10.

L.S.A., aged 60 years, is incapacitated by paralysis agitans. Only income £30 a year from Epsom College. Four children, aged 18 to 12. Relieved twice, £36. Voted £18.

Widow, aged 59 years, of M.R.C.S. No income. Slight help from children; health indifferent. Relieved ten times, £111. Voted £12.

Daughter, aged 69 years, of late M.R.C.S. Has supported herself for many years as a governess. Now dependent on a small weekly allowance from a benevolent institution. Relieved once, £12. Voted £12.

Widow, aged 47 years, of M.B., C.M. Edin. Income £16 a year, and is allowed a small weekly sum by a relation. Takes boarders. Seven children, of whom six are still at school; health indifferent. Relieved nine times, £102. Voted £12.

Widow, aged 48 years, of M.R.C.S., L.S.A. Has been a housekeeper for some years, but salary has been insufficient for the bringing up of her two children, who are still barely self-supporting. Relieved nine times, £110. Voted £5.

Daughter, aged 62 years, of late M.R.C.S. No income; occasional slight help from friends. Relieved once, £12. Voted £12.

LYNN THOMAS AND SKYRME FUND.

THE following subscriptions have been received between April 25th and May 1st by Mr. William Sheen, M.S. Lond., F.R.C.S. Eng. (2, St. Andrew's-crescent, Cardiff), honorary secretary to the fund.

Subscriber of Five Guineas.

ASSOCIATION OF SCOTTISH MEDICAL DIPLOMATES.—The annual dinner of this association will be held at the Hotel Waldorf, Aldwych, London, W.C., on Tuesday, May 26th, at 7.15 for 7.30 P.M., under the chairmanship of the President, Dr. David Walsh. Ladies are invited and any holder of a Scottish qualification will be welcomed. Tickets, 10*s.* 6*d.* each (exclusive of wine), may be obtained from the honorary secretary, Dr. Arthur Harries, 11, Chandos-street, Cavendish-square, London, W.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 8th, 1830.

INVENTION OF THE DILATOR.

To the Editor of THE LANCET.

SIR,—I beg leave, through the medium of your publication, to make a few remarks upon a little instrument which has been ycleped the dilator, and which has been assumed as their own invention by certain persons, without reasonable confession of the original suggestor. This instrument has been pompously introduced into a late publication on mechanics, and ostensibly constitutes the ground-work of a publication, in which it is represented as a personal discovery. In 1811, on the way home from the East Indies, I had a gentleman under my charge who was troubled with stricture. In the course of reflection on the subject, it occurred to me, that it would be very possible to make an instrument which could be dilated, or widened, at any given point of its length, or that a greater or shorter extent of its length might be made capable of dilatation, either abruptly or gradually, from the cylindrical portion of the instrument. I illustrated a tool of this kind upon paper, and mentioned of what materials it might be constructed, to the person referred to; he instantly perceived the possibility of such a contrivance, and that it might be more or less serviceable. On my return to Britain, I intended to have said something on the subject in a periodical publication, but I concluded that it would not be particularly beneficial, and would lead only to quackery and humbug. I saw also a number of objections which might be instituted against it, and therefore very considerable probability of its comparative uselessness. On reaching London, in the summer of the same year, I mentioned the plan to the author of the Elements of Mechanics and Medical Physics, and stated, expressly, several substances of which the dilator might be composed. He appeared to catch at the suggestion with eagerness, and, if I mistake not, immediately entered it in a memorandum. For some reason, perhaps the "*fidem dabo*," he must have conveyed the hint to his brother (who has published a book on this trifle), as the former durst not avowedly be concerned in the thing himself. I believe it has done some good to the two brothers, but none to its legitimate father. The original proposer, actuated by sincerity and honesty of principle, declined executing his design, and has not obtained even the concession of an acknowledgment. A. SIMPSON, M.D.

Great Russell Street, April, 1830.

MEDICINE AND THE LAW.

Medical Fees: an Important Decision.

AT Ulverston (Lancashire) county court on April 28th Judge Steavenson gave an important judgment that cannot fail to be of interest to medical practitioners generally. The plaintiff was Mr. R. H. Beardsley of Grange-over-Sands and he sued Mrs. Willan of Holme Island for £80 17*s*. 6*d*. for medical attendance and medicines. The defence was that more visits had been paid than were necessary and that the charges for the same were unnecessarily high. It was given in evidence that Holme Island was rated at £165 gross and £140 net. Dr. A. Carmichael of Barrow-in-Furness said that in his opinion the plaintiff's account was a reasonable one and that 10*s*. per visit, with medicines extra, was a proper charge to make for attendance at a house of the description of Holme Island. Dr. R. O. Bowman of Ulverston gave similar evidence and Dr. R. G. Alexander of Halifax, who had been called in in consultation with plaintiff, said that the defendant was very ill indeed at the time when he saw her and that the visits paid were not too numerous but were absolutely necessary. It was owing to the skill with which she had been treated that she was alive now. Mr. Beardsley supported his account in evidence, giving particulars showing that for ordinary visits 10*s*. had been paid and for consultations £1 1*s*. plus the ordinary 10*s*. charge, which he always considered was the proper charge to make for a consultation. In reply to the judge the plaintiff said that he was not a Licentiate of the Society of Apothecaries. He was a Licentiate of the Royal Colleges of Physicians and Surgeons, Edinburgh, and a Licentiate of the Faculty of Physicians and Surgeons, Glasgow. It was stated that £50 had been offered in payment of the account and refused, and that as to £5 5*s*. of the claim, if the defendant pleaded the Statute of Limitations, it was statute barred. For the defence Dr. R. Lowther and Mr. O. Gwatkin medical practitioners at Grange-over-Sands were called and said that in their opinion the account was unreasonably high. They admitted, however, that they did not consider 10*s*. a visit and the charge for medicines unreasonable, considering that Holme Island was one and three-quarter miles from the plaintiff's surgery and that Mr. Beardsley had by stipulation to attend at 10.30 each morning which would doubtless be inconvenient to him and disarrange his ordinary work. Judge Steavenson delivered a considered judgment after the luncheon interval. He said he considered from the evidence that 10*s*. per visit was a proper charge, considering the value of the house, its distance from the plaintiff's surgery, and the stipulation that he was to attend the patient at a particular time. He accepted the evidence of Dr. Carmichael that a consultation fee was double the ordinary fee, which in this case must therefore be fixed at 20*s*. He did not consider the qualifications held by Mr. Beardsley entitled him to charge for medicines and that part of the claim must come out. The claim would be reduced by £11 14*s*. 3*d*. for medicines and excess charged for consultations, and the £5 5*s*. that was statute barred, leaving a balance of £63 18*s*. 6*s*. £50 had already been paid—being in the hands of the plaintiff's solicitor—so he therefore gave judgment for £13 18*s*. 6*d*., with costs on the higher (B) scale, with allowances for witnesses.

"*The Separate Existence*" *of the Newly Born Child.*

At the recent discussion on Infanticide at the Medico-Legal Society several speakers referred to the ingenuity and quibbles of defending counsel which made it impossible, in connexion with a charge of infanticide, to determine, in the absence of the direct evidence of an eye-witness, whether a child had had "a separate and independent existence" before its life ceased. "A separate and independent existence" has been ruled in court at different periods to indicate at least four physiologically different conditions. The first and simplest requirement is the physical separation of the body of the child from the body of the mother, so that the child is wholly born into the world and is thus a full subject of the King; in this connexion it has been decided that the umbilical cord need not have been severed. The second view, which in practice was accepted for many years, was tested by the question: "Has the child breathed?" The fallacy of this test was insisted upon by those who alleged that the child might have breathed before it was completely born—that is, before it became a subject capable of coming within the technical definition of murder; many years ago the inferential physical test, based upon the performance of the respiratory function, known as docimasia pulmonum was derided as "that hydrostatic humbug." The third view of "separate existence," which several modern judicial statements have favoured, has been that in order to inaugurate such an independent being in law the circulations of the mother and of the child must be distinct. All such legal pronouncements are somewhat reminiscent of a pristine physiology and exhibit a confused knowledge as to the exact nature of the symbiotic relations of the respective circulatory systems before birth; physically, if not physiologically, it may be said that these systems, both originally and finally, are as separate as that of the sitting hen from that of the hatching chick within the egg-shell. To add to this apparent diversity of judicial opinion it may be said, from the physiological standpoint, that no child really commences its separate existence until it breathes, for until that act it is merely surviving on the nutriment already acquired by osmosis and diffusion from the mother's uterine blood-stream; hence children who have been completely born in an asphyxiated condition and who have been subsequently revived, with or without artificial aid, may be said to have commenced a real independent existence only concurrently with the first inspiration; conversely, any child gasping for air, whether in the outside world or in utero or in vagina, proclaims by that very respiratory act that it is announcing its true separate physiological existence. The fourth view, and

"Helen Graham Chalmers and Her Mother" (300), is full of light and air and colour. In Gallery No. 5 Mr. C. W. Wyllie's (347), also called "The Return," is worthy of close study and comparison with Mr. Brangwyn's treatment of a similar idea; and Mr. Sims in (361) has, we are glad to say, captured the Chantrey Fund by "The Fountain," a study of falling waters, light, and nymphs, which shows the artist in the best sense to be truly νυμφόληπτος. Our space is too limited to allow us to do more than mention a few of the remaining pictures. In (417) Mr. George Henry has a charming portrait study which he calls "Silk and Ermine," and another striking portrait is (433), H.H. the Maharajah Orocha, by Mr. Herbert Olivier. Mr. George Harcourt (480) exhibits a brilliant piece of work entitled "Supper in Summer Time." In the room popularly known as the "Gem Room" Miss C. M. Wood has a very clever study of the splendid colours shown by various copper ores (683). Two adjoining pictures in Gallery No. 10 should on no account be missed, these being Nos. (877) and (878), by Mr. Raven Hill and Mr. G. Sherwood Hunter respectively, the former being a study of a lady seated in subdued light at a piano, and the other a Brittany "First Communion" with a charming effect of light from a hundred candles mixing with the daylight. Mr. E. A. Hornel in (897) has a picture singularly reminiscent of his exhibit in the New Gallery, and in (975) Mr. W. W. Ouless shows a good portrait of Mr. Pridgin Teale. Of the water-colours we have only space to notice the President's little picture of Amat Forest, Ross-shire.

Of the sculpture we must first mention (1848) Mr. Herbert Frampton's bust of Dr. J. Hughlings Jackson, which is to be placed in the Hospital for Epilepsy and Paralysis, Queen-square, Bloomsbury, London, W.C. Mr. F. Lynn Jenkins' group (1851), "The Ides of March," shows well the lifelessness of Cæsar's body as opposed to the two senators straining to support it. Other notable statues are (1820) Mr. Harold Parker's "Ariadne" and (1974) Mr. Bertram Mackennal's "Diana," two beautiful nudes which have been acquired for the nation by the Chantrey Fund, which has also rightly acquired Mr. C. L. Hartwell's vigorous little bronze of elephants which he calls "A Foul in the Giants' Race." Lastly, we must mention (1973) Mr. Goscombe John's model of altar tomb and effigy of the late Marquis of Salisbury, and (1976) Mr. F. Derwent Wood's "Psyche." On the whole we consider that this year's Academy exhibition is one of the most interesting of those which have been held during recent years.

BRITISH MEDICAL BENEVOLENT FUND.

AT the April meeting of the committee 20 cases were considered and grants amounting to £202 were made to 18 of the applicants, two cases being postponed for further inquiry. Three vacancies for annuitants of £20 were filled by selected candidates. Appended is an abstract of the cases relieved:—

Daughters, aged 54 and 47 years, of late M.R.C.S. Since loss of means some years ago through the dishonesty of a trustee applicants have supported themselves by acting as companions, &c., but just at present have no engagements. Voted £10.

L.R.C.P., L.R.C.S. Edin., aged 48 years. Had one eye enucleated 12 years ago and has since lost sight in the other. No income. Wife lets lodgings. Five children, aged 13 to eight years. Voted £18.

Four children, the eldest 13 years and the youngest one month, who have lost both parents during the current year. Are given a home by maternal grandfather, a clergyman with small means and a large family. Voted £10, with leave to apply again in six months.

Daughter, aged 65 years, of late M.D. Lond. Only income £4 a year from savings during 40 years of teaching. Now endeavours to support herself by knitting and needlework. Voted £12.

Daughter, aged 57 years, of late L.S.A. Lets lodgings and has to support a sister incapacitated by ill-health. Voted £12.

Daughter, aged 31 years, of late L.R.C.P., L.R.C.S. Edin. Has maintained herself as a nurse-companion but is now incapacitated by rheumatoid arthritis. No income. Voted £10.

Widow, aged 57 years, of M.D. Edin. Has a post as housekeeper but at present has to support a daughter who is temporarily incapacitated. Voted £5.

Widow, aged 60 years, of M.R.C.S. No income. Children unable to help and health very bad. Relieved twice, £24. Voted £12.

Widow, aged 45 years, of L.R.C.P., L.R.C.S. Edin. No income. Two sons who are sailors only just self-supporting. Health very indifferent. Relieved four times, £39. Voted £12.

Daughter, aged 58 years, of late M.R.C.S., who was an annuitant of this Fund. Is given a home in exchange for services as working housekeeper, but receives no salary. Relieved seven times, £108. Voted £10.

Daughter, aged 58 years, of late M.D. Aberd. Endeavours to support herself by teaching music, but finds increasing difficulty in obtaining pupils. Relieved once, £10. Voted £10.

Widow, aged 53 years, of M.B. Aberd., whose means were exhausted by a long illness which preceded his death. For some time past applicant has held a post as nurse-companion but has been obliged to give it up on account of ill-health and at present is incapacitated. Children just self-supporting. Relieved once, £5. Voted £10.

L.S.A., aged 60 years, is incapacitated by paralysis agitans. Only income £30 a year from Epsom College. Four children, aged 18 to 12. Relieved twice, £36. Voted £18.

Widow, aged 59 years, of M.R.C.S. No income. Slight help from children; health indifferent. Relieved ten times, £111. Voted £12.

Daughter, aged 69 years, of late M.R.C.S. Has supported herself for many years as a governess. Now dependent on a small weekly allowance from a benevolent institution. Relieved once, £12. Voted £12.

Widow, aged 47 years, of M.B., C.M. Edin. Income £16 a year, and is allowed a small weekly sum by a relation. Takes boarders. Seven children, of whom six are still at school; health indifferent. Relieved nine times, £102. Voted £12.

Widow, aged 48 years, of M.R.C.S., L.S.A. Has been a housekeeper for some years, but salary has been insufficient for the bringing up of her two children, who are still barely self-supporting. Relieved nine times, £110. Voted £5.

Daughter, aged 62 years, of late M.R.C.S. No income; occasional slight help from friends. Relieved once, £12. Voted £12.

LYNN THOMAS AND SKYRME FUND.

ASSOCIATION OF SCOTTISH MEDICAL DIPLOMATES.—The annual dinner of this association will be held at the Hotel Waldorf, Aldwych, London, W.C., on Tuesday, May 26th, at 7.15 for 7.30 P.M., under the chairmanship of the President, Dr. David Walsh. Ladies are invited and any holder of a Scottish qualification will be welcomed. Tickets, 10*s.* 6*d.* each (exclusive of wine), may be obtained from the honorary secretary, Dr. Arthur Harries, 11, Chandos-street, Cavendish-square, London, W.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 8th, 1830.

INVENTION OF THE DILATOR.

To the Editor of THE LANCET.

SIR,—I beg leave, through the medium of your publication, to make a few remarks upon a little instrument which has been ycleped the dilator, and which has been assumed as their own invention by certain persons, without reasonable confession of the original suggester. This instrument has been pompously introduced into a late publication on *mechanics*, and ostensibly constitutes the ground-work of a publication, in which it is represented as a personal discovery. In 1811, on the way home from the East Indies, I had a gentleman under my charge who was troubled with stricture. In the course of reflection on the subject, it occurred to me, that it would be very possible to make an instrument which could be dilated, or widened, at any given point of its length, or that a greater or shorter extent of its length might be made capable of dilatation, either abruptly or gradually, from the cylindrical portion of the instrument. I illustrated a tool of this kind upon paper, and mentioned of what materials it might be constructed, *to the person* referred to; he instantly perceived the possibility of such a contrivance, and that it might be more or less serviceable. On my return to Britain, I intended to have said something on the subject in a periodical publication, but I concluded that it would not be particularly beneficial, and would lead only to quackery and humbug. I saw also a number of objections which might be instituted against it, and therefore very considerable probability of its comparative uselessness. On reaching London, in the summer of the same year, I mentioned the plan to the author of the Elements of Mechanics and Medical Physics, and stated, expressly, several substances of which the dilator might be composed. He appeared to catch at the suggestion with eagerness, and, if I mistake not, immediately entered it in a memorandum. For some reason, perhaps the "*fidem dabo*," he must have conveyed the hint to his brother (who has published a book on this trifle), as the former durst not avowedly be concerned in the thing himself. I believe it has done some good to the two brothers, but none to *its legitimate father*. *The original* proposer, actuated by sincerity and honesty of principle, declined executing his design, and has not obtained even the *concession* of an acknowledgment.

A. SIMPSON, M.D.

Great Russell Street, April, 1830.

MEDICINE AND THE LAW.

Medical Fees: an Important Decision.

AT Ulverston (Lancashire) county court on April 23th Judge Steavenson gave an important judgment that cannot fail to be of interest to medical practitioners generally. The plaintiff was Mr. R. H. Beardsley of Grange-over-Sands and he sued Mrs. Willan of Holme Island for £80 17s. 6d. for medical attendance and medicines. The defence was that more visits had been paid than were necessary and that the charges for the same were unnecessarily high. It was given in evidence that Holme Island was rated at £165 gross and £140 net. Dr. A. Carmichael of Barrow-in-Furness said that in his opinion the plaintiff's account was a reasonable one and that 10s. per visit, with medicines extra, was a proper charge to make for attendance at a house of the description of Holme Island. Dr. R. O. Bowman of Ulverston gave similar evidence and Dr. R. G. Alexander of Halifax, who had been called in in consultation with plaintiff, said that the defendant was very ill indeed at the time when he saw her and that the visits paid were not too numerous but were absolutely necessary. It was owing to the skill with which she had been treated that she was alive now. Mr. Beardsley supported his account in evidence, giving particulars showing that for ordinary visits 10s. had been paid and for consultations £1 1s. plus the ordinary 10s. charge, which he always considered was the proper charge to make for a consultation. In reply to the judge the plaintiff said that he was not a Licentiate of the Society of Apothecaries. He was a Licentiate of the Royal Colleges of Physicians and Surgeons, Edinburgh, and a Licentiate of the Faculty of Physicians and Surgeons, Glasgow. It was stated that £50 had been offered in payment of the account and refused, and that as to £5 5s. of the claim, if the defendant pleaded the Statute of Limitations, it was statute barred. For the defence Dr. R. Lowther and Mr. O. Gwatkin medical practitioners at Grange-over-Sands were called and said that in their opinion the account was unreasonably high. They admitted, however, that they did not consider 10s. a visit and the charge for medicines unreasonable, considering that Holme Island was one and three-quarter miles from the plaintiff's surgery and that Mr. Beardsley had by stipulation to attend at 10.30 each morning which would doubtless be inconvenient to him and disarrange his ordinary work. Judge Steavenson delivered a considered judgment after the luncheon interval. He said he considered from the evidence that 10s. per visit was a proper charge, considering the value of the house, its distance from the plaintiff's surgery, and the stipulation that he was to attend the patient at a particular time. He accepted the evidence of Dr. Carmichael that a consultation fee was double the ordinary fee, which in this case must therefore be fixed at 20s. He did not consider the qualifications held by Mr. Beardsley entitled him to charge for medicines and that part of the claim must come out. The claim would be reduced by £11 14s. 3d. for medicines and excess charged for consultations, and the £5 5s. that was statute barred, leaving a balance of £63 18s. 6s. £50 had already been paid—being in the hands of the plaintiff's solicitor—so he therefore gave judgment for £13 18s. 6d., with costs on the higher (B) scale, with allowances for witnesses.

"The Separate Existence" of the Newly Born Child.

At the recent discussion on Infanticide at the Medico-Legal Society several speakers referred to the ingenuity and quibbles of defending counsel which made it impossible, in connexion with a charge of infanticide, to determine, in the absence of the direct evidence of an eye-witness, whether a child had had "a separate and independent existence" before its life ceased. "A separate and independent existence" has been ruled in court at different periods to indicate at least four physiologically different conditions. The first and simplest requirement is the physical separation of the body of the child from the body of the mother, so that the child is wholly born into the world and is thus a full subject of the King; in this connexion it has been decided that the umbilical cord need not have been severed. The second view, which in practice was accepted for many years, was tested by the question: "Has the child breathed?" The fallacy of this test was insisted upon by those who alleged that the child might have breathed before it was completely born—that is, before it became a subject capable of coming within the technical definition of murder; many years ago the inferential physical test, based upon the performance of the respiratory function, known as docimasia pulmonum was derided as "that hydrostatic humbug." The third view of "separate existence," which several modern judicial statements have favoured, has been that in order to inaugurate such an independent being in law the circulations of the mother and of the child must be distinct. All such legal pronouncements are somewhat reminiscent of a pristine physiology and exhibit a confused knowledge as to the exact nature of the symbiotic relations of the respective circulatory systems before birth; physically, if not physiologically, it may be said that these systems, both originally and finally, are as separate as that of the sitting hen from that of the hatching chick within the egg-shell. To add to this apparent diversity of judicial opinion it may be said, from the physiological standpoint, that no child really commences its separate existence until it breathes, for until that act it is merely surviving on the nutriment already acquired by osmosis and diffusion from the mother's uterine blood-stream; hence children who have been completely born in an asphyxiated condition and who have been subsequently revived, with or without artificial aid, may be said to have commenced a real independent existence only concurrently with the first inspiration; conversely, any child gasping for air, whether in the outside world or in utero or in vagina, proclaims by that very respiratory act that it is announcing its true separate physiological existence. The fourth view, and perhaps the most practical and satisfactory of all, is that any newly born infant who exhibits muscular contractions—be they of the heart and blood-vessels, the chest, the lips, or even of the thumbs or little toes—is to be accounted as "a reasonable creature in being and within the King's Peace," alike for the purposes of the civil and of the criminal law. The present law presumes that a newly born child found dead was born dead—that is, the fact that it lived must be definitely proved if alleged; a century ago it was always necessary for a mother, in the case of her bastard child being found dead, to prove that it was born lifeless, otherwise she was chargeable with having taken its life.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9225 births and 4896 deaths were registered during the week ending May 2nd. The annual rate of mortality in these towns, which had been equal to 15·2 and 15·4 per 1000 in the two preceding weeks, further rose to 15·7 in the week under notice. During the first five weeks of the current quarter the annual death-rate in these towns has, however, only averaged 15·7 per 1000, and in London it did not exceed 15·5 during the same period. The lowest annual death-rates in the 76 towns during the week under notice were 7·4 in Aston Manor, 7·5 in Leyton, 8·0 in King's Norton, and 9·1 in Walthamstow, all being suburban districts; the rates in the other towns ranged upwards to 23·0 in Merthyr Tydfil and in Bury, 23·8 in Hanley, and 25·6 in Swansea. The death-rate in London during the week was equal to 16·0 per 1000. The 4896 deaths in the 76 towns during the week showed a further increase of 116 upon the low numbers returned in the two previous weeks, and included 381 which were referred to the principal epidemic diseases, against 382 and 376 in the two preceding weeks; of these, 128 resulted from measles, 122 from whooping-cough, 52 from diarrhœa, 38 from diphtheria, 29 from scarlet fever, and 12 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases were equal to an annual rate of 1·2 per 1000, corresponding with the rate in each of the two preceding weeks; the rate from the same diseases in London was equal to 1·4. No death from any of these epidemic diseases was registered last week in Leicester, East Ham, Derby, Leyton, Halifax, Wolverhampton, or in 14 other smaller towns; the annual death-rates from these diseases, however, ranged upwards to 3·5 in Preston, 3·7 in Salford, 4·3 in Croydon, and 4·9 in Stockton-on-Tees. The fatal cases of measles in the 76 towns, which had been 127 and 101 in the two previous weeks, rose again last week to 128; the highest death-rates from this disease in these towns last week were 2·0 in Burnley, 2·3 in South Shields, 2·6 in Croydon, 2·9 in Stockton-on-Tees, and 3·5 in Preston. The 122 deaths from whooping-cough showed a further decline from the numbers in recent weeks; they caused death-rates, however, equal to 1·3 in Devonport and in Salford, 1·5 in Bootle and in Warrington, 1·6 in Rotherham, and 2·0 in Sunderland. The 52 deaths attributed to diarrhœa showed a considerable increase upon recent weekly numbers. The fatal cases of diphtheria, however, declined to 38, and were fewer than in any previous week of this year; they included 10 in London, three in Manchester, and two each in Bristol and in Bradford. The 29 deaths from scarlet fever also showed a decline, but included 12 in London, three in Salford, two in Liverpool, and two in West Bromwich. The 12 deaths referred to "fever," including three in Liverpool, were fewer than in any previous week of this year. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily declined in the 21 preceding weeks from 5581 to 2861, had increased to 2928 on May 2nd; 368 new cases having been admitted to these hospitals during the week under notice, against 297, 328, and 332 in the three preceding weeks. The deaths in London referred to pneumonia and to other diseases of the respiratory organs, which had been 274 and 301 in the two preceding weeks, declined again to 281 in the week under notice, but exceeded by 15 the corrected average number in the corresponding week of the five years 1903-07. The 19 deaths directly referred to influenza in London showed a further decline from the numbers in recent weeks. The causes of 58, or 1·2 per cent., of the deaths registered in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, Bristol, West Ham, Leeds, Newcastle-on-Tyne, Nottingham, and in 41 other smaller towns; 10 uncertified causes of death were, however, registered in Liverpool, seven in Birmingham, and three both in South Shields and in Gateshead during the week under notice.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 16·4 and 18·8 per 1000 in the two preceding weeks, was 18·7 in the week ending May 2nd, and exceeded by 3·0 the mean rate during the same week in the 76 large English towns. Among the eight Scotch towns, the death-rate during the week under notice ranged from 14·4 and 14·8 in Paisley and Leith, to 20·9 in Glasgow and 23·7 in Perth. The 658 deaths in these eight towns were fewer by five than the number in the previous week, and included 68 which were referred to the principal epidemic diseases, against 77 in each of the two preceding weeks; of these, 24 resulted from measles, 20 from whooping-cough, 13 from diarrhœa, five from "fever," and three both from scarlet fever and diphtheria, but not one from small-pox. These 68 deaths were equal to an annual rate of 1·9 per 1000, the mean rate from the same diseases in the 76 English towns during the same week not exceeding 1·2. The 24 fatal cases of measles in the Scotch towns showed a further decline of 10 from the numbers returned in recent weeks, and included 13 in Glasgow, five in Edinburgh, three in Paisley, and two in Aberdeen. The deaths from whooping-cough, on the other hand, which had been 13, 18, and 12 in the three preceding weeks, rose again to 20 last week, of which 11 occurred in Glasgow, three in Edinburgh and in Aberdeen, and two in Dundee. Of the 13 deaths attributed to diarrhœa nine were returned in Glasgow. The five deaths referred to "fever" were all certified as cerebro-spinal meningitis, and all occurred in Glasgow. The three fatal cases of scarlet fever corresponded with the number in the previous week, while the three referred to diphtheria showed a decline of four, and included two in Glasgow and one in Paisley. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 121 and 113 in the two preceding weeks, further declined to 107 in the week under notice, and were 20 below the number returned in the corresponding week of last year. The causes of 25, or 3·8 per cent., of the deaths in these eight towns during the week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death in the same week did not exceed 1·2 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 23·1 and 21·1 per 1000 in the two preceding weeks, rose again to 21·9 in the week ending May 2nd. During the first five weeks of the current quarter the death-rate in Dublin averaged 22·9 per 1000; the mean rate during the same period did not exceed 15·5 in London and 16·0 in Edinburgh. The 166 deaths of Dublin residents registered in the week under notice showed an increase of six upon the number returned in the previous week, and included ten which were referred to the principal epidemic diseases, showing an increase of three upon the number in each of the two previous weeks. These ten deaths were equal to an annual rate of 1·3 per 1000, the rate during the week from the same diseases being 1·4 in London and 1·3 in Edinburgh. Of these ten deaths from epidemic diseases in Dublin three resulted from whooping-cough, three from diarrhœa, two from diphtheria, and one each from "fever" and measles, but not one either from scarlet fever or small-pox. The two fatal cases of diphtheria were the first recorded in Dublin since the middle of March. The 166 deaths from all causes in the city during the week included 28 of infants under one year of age and 46 of persons aged upwards of 60 years; both these numbers exceeded those in the previous week. Six inquest cases and three deaths from violence were registered, and 75, or 45·2 per cent., of the deaths occurred in public institutions. The causes of three, or 1·8 per cent., of the deaths registered in the city during the week under notice were not certified; the causes of all the 1474 deaths in London last week were duly certified, while in Edinburgh 6·0 per cent. of the causes of death were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified :—Fleet-Surgeons: J. H. Stenhouse to the *President*, additional, for Greenwich Hospital School and R.N. College; W. Bett to the *Leviathan;* E. S. M. Nepean to the *Victory*, additional, for Portsmouth Dockyard; and J. Shand to the *Africa*. Staff-Surgeons: R. D. Jameson to the *President*, additional, for three months' course at the Dreadnought Hospital; F. H. Nimmo to the *Alexandra*, on commissioning; F. R. Mann to the *Excellent;* and H. W. M. Rees to the *Orion*. Surgeons: R. H. St. B. E. Hughes to Malta Hospital; W. C. B. Smith to the *Vernon*, additional, for the *Niger;* A. D. C. Cummins to the *Dreadnought;* and R. W. B. Hall to the *Enchantress*.

ROYAL ARMY MEDICAL CORPS.

Major George Dansey-Browning, from the Seconded List, to be Major (dated April 5th, 1908).

The following officers have been attached to the depôt at Aldershot for a special course of instruction under Major J. D. Ferguson, Chief Instructor :—Captain C. P. Connolly, Captain H. H. Kiddle, Captain R. H. Lloyd, Captain W. A. Woodside, and Lieutenant J. C. L. Hingston.

Captain A. J. W. Wells has been posted to the Cambridge Hospital, Aldershot, for duty. Lieutenant-Colonel W. Rowney has been appointed Medical Officer in charge of the Connaught Hospital, North Camp, Aldershot, and to command No. 2 Company.

DEATHS IN THE SERVICES.

Deputy Surgeon-General William Silver Oliver, A.M.D., retired pay, at Farnborough Park recently, aged 72 years. He entered the service as assistant surgeon in 1857; became surgeon in 1872; surgeon-major in 1873; brigade-surgeon in 1882; and retired with the honorary rank of deputy surgeon-general the following year. He served in the campaign in Rohilkund in 1858, including the actions of Bugawalla and Nugena, the relief of Moradabad, the action on the Dojura, the assault and capture of Bareilly, the attack and bombardment of Shahjehanpore, the capture of Fort Bunnai, the pursuit of the enemy to the left bank of the Goomtee, the destruction of Fort Mahomdee, the attack on and destruction of Shahabad, and the action of Bungkagong. He also served in the Oude campaign, including the actions of Pusgaon and Rissoolpore, the attack and capture of Fort Mittowlie, and the actions at Mehundee and Biswah (mentioned in despatches and medal). He served with the 1st Battalion 60th Rifles in the Red River Expedition in 1870.

THE SPECIAL RESERVE OF OFFICERS.

A special Army Order containing a Royal Warrant has recently been issued authorising the formation of a Special Reserve of Officers and a further step has consequently been taken towards the organisation of the Special Reserve. The Army Order in question dealing with all branches of the service is necessarily a long one, but it contains many points directly bearing upon the Royal Army Medical Corps and should consequently be consulted by those whose interests may become affected. The following paragraphs should be noted :—

> RETIREMENT.
>
> An officer appointed to our Royal Army Medical Corps *or* Army Veterinary *Corps shall relinquish his* commission on reaching the age of 55.
>
> EMOLUMENTS IN TIME OF PEACE.
>
> Servant allowances shall not be issuable except to an officer of our Royal Engineers, Army Service Corps, Royal Army Medical Corps, or Army Veterinary Corps, who is attending an authorised course at a school of instruction where a soldier servant cannot be provided.
>
> On being gazetted to a commission on probation a Special Reserve officer shall be granted an outfit allowance of £20, if on probation for our Army Service Corps, Royal Army Medical Corps, or Army Veterinary Corps, provided that he shall undertake in writing that, in the event of his failing from any cause to complete a period of four years' service in the Special Reserve from the date of joining, he will refund one-fourth of the allowance for each year or portion of a year by which his service falls short of such period. In cases of sickness *the* refund, or a part thereof, may be waived at the discretion of our Army Council. This allowance shall not be granted to any officer who is a candidate *for* a permanent commission on the active list of our Regular Forces.
>
> After the date of this Warrant no further commissions will be granted in the Army Medical Reserve under the conditions of Articles 640-644 of the Pay Warrant, 1907.

ROYAL ARMY MEDICAL CORPS CAMPS.

A camp of instruction for the Royal Army Medical Corps is to be formed at Salisbury Plain on June 1st, lasting for about six weeks. The previous camps for the Royal Army Medical Corps have proved so successful in a training sense that they will now be held annually. A camp of instruction for the field training of the Royal Army Medical Corps will also be held at Bulford from June 1st to July 11th. The approximate strength of the party undergoing instruction will be ten officers and 182 of other ranks drawn from the various out-stations of the Southern Command.

Correspondence.

"Audi alteram partem."

EPILEPSY AND MIGRAINE.

To the Editor of THE LANCET.

SIR,—In view of the recent publication of Sir W. Gowers's lectures on the Borderland of Epilepsy, the following cases illustrative of an intimate relationship between migraine and epilepsy may be of interest :—

CASE 1.—A woman, aged 42 years, on the appearance of the catamenia at the age of 15 years, began to suffer from fits of an epileptic character, which continued on an average once a month, till the age of 21 years, when they ceased altogether. Usually before the onset of the fit she suffered from headache. On the cessation of the fits, however, the headaches became more and more frequent and gradually assumed a definitely migrainous character. When an attack occurs she usually wakes early in the morning with her head feeling like an iron ball and the shoulders and neck as if in an iron vice, then she sees silver specks and zig-zag lines before the eyes, followed by severe pain in the forehead and vomiting a few hours later, after which she is quite well again. Thus migraine has become the predominant feature of a case originally epileptic. The more usual sequence of events, however, is for a patient with migraine to become epileptic. In this case the father and a paternal aunt suffered from gout, a common antecedent of migraine.

CASE 2.—A woman, aged 25 years, when 19 years old, had an epileptic fit for the first time, following a fright. Since then she has had a fit on an average every four months and once as many as ten in a day. The aura preceding the fit is peculiar in that it lasts about an hour and is of a migrainous type; then there are zig-zag lines of flame in front of the left eye, which then pass to the right, the left arm feels drawn and the left heel as if glued to the ground. This condition lasts for about an hour, during all which time she has a severe headache across the eyes and back of the head. After the fit she always vomits and is free from headache. The case shows a curious blending of epilepsy and migraine. Both the duration and character of the aura seem to be migrainous and the vomiting belongs to migraine rather than to epilepsy. It would seem as though an ordinary attack of migraine were interrupted, so to speak, by the motor phenomena of epilepsy. On the other hand, since the commencement of these attacks the patient has become very irritable, a feature suggestive of epilepsy, not of migraine.

CASE 3.—A woman, aged 19 years, when 11 years old, began to suffer from epileptic fits which continued for a few months. At the age of 17 years she began to have headaches of a migrainous character, waking up in the morning with a visual spectra—teichopsia, half an hour later she has a headache lasting 12 hours, followed by sickness. These attacks occur about once a fortnight. Lately the epileptic seizures have begun again and exhibit almost as marked a periodicity as the migrainous headaches, always beginning about 5 A.M. and seeming to take the place of the sensory attack. The father suffers from asthma, a disease which has affinities with both epilepsy and migraine.

CASE 4.—A boy, aged six years, for the last three years has suffered from paroxysms of headaches once a week. The headache generally begins in the forenoon, gradually growing worse towards the evening; usually he is sick at an early stage of the headache and before being sick he says that everything seems "to go red in front of him." The following day he is tired and languid, but there is no headache. Within the last few months he has had two epileptic fits and the paroxysmal headaches have become less frequent. Often on the evening prior to the migrainous attacks he has had an attack of night-terrors, which are sometimes suggestive of epilepsy.

Some observers have noticed instead of the usual periodicity of migraine a continual succession of the attacks which has been called the "status hemicranicus" by the school of Charcot, on the analogy of the "status epilepticus." Möbius quotes a case in which the patient had five attacks of migraine in five successive days. After an interval of some months there was another series, which led to a kind of stupor, and finally there was a third series consisting of nine attacks in four days; at the same time there was a complete hemiplegia.[1] Kraft-Ebing speaks of epileptic hemicrania and hemicranial epilepsy having the same visual aura and seems to imply that there is but one disease, though sometimes migrainous, at others epileptic symptoms predominated in a given case; he says that the visual aura may occur alone or end in a hemicranical or epileptic attack or both.[2]

I am, Sir, yours faithfully,

Green-street, W., May 4th, 1908. R. O. MOON.

WORTH'S ADVANCEMENT OPERATION.

To the Editor of THE LANCET.

SIR,—I have at least as great an objection to *ex cathedrâ* statements as Mr. Claud Worth and I may point out that anonymity finds its justification in the elimination of personal motives which are, at any rate, absent in the present instance. The fallacy which in my opinion characterises Mr. Worth's in common with many other advancement operations is that in the ordinary operation the stitches tear out through the muscle and thus lead to an unsatisfactory result. I am convinced that failure is not due to the stitches tearing out through the muscle, which is supported by resistant connective tissue, but to their giving way at their anterior attachment. Here, unless a firm hold is obtained upon the episcleral tissue the stitch is almost certain to cut out, no matter how secure may be its attachment to the muscle. Mr. Worth has mentioned the chief objection to his operation, and if it is carefully considered it is no small one. His knots strangle the lateral parts of the muscle which must necessarily atrophy and are further lacerated in removing the stitches. For my part I am convinced that the secret of success in advancement operations is obtaining a firm hold on the episcleral tissue. I do not propose to pit any individual surgeon's practical experience against Mr. Worth's, for in such matters there is but little faith to be put in personal authority. It is the duty of every surgeon to weigh the advantages and disadvantages of any given procedure and to adopt the method which appears to him to be best.

I am, Sir, yours faithfully,

May 2nd, 1908. *YOUR REVIEWER.*

THE ROYAL SOCIETY OF MEDICINE AND THE MEDICAL SOCIETY OF LONDON.

To the Editor of THE LANCET.

SIR,—I should like to suggest through the medium of your columns, to the Fellows of the Medical Society of London, that the time has come to consider further whether they are acting in the best interests of the society as a whole in holding aloof from union with the Royal Society of Medicine.

The reasons, so far as one could gather, which led to their attitude at the time of the inception of the latter society were mainly financial but I think that the remarkable success which has attended the formation of the Royal Society must have put any question of its financial stability quite out of court, while sentimental considerations which may not unnaturally have weighed with the older members should not be allowed to assume an undue prominence. Apart from my own personal feelings, conversation with other Fellows of the society has shown me that a strong feeling exists (which in many cases will develop into withdrawal from membership) that the interests of the society and of its members would have been better served by union, and certainly the opinion of the Fellows which was taken by means of postcards showed a very large majority in favour of amalgamation. The general meeting which was called to consider the question was, however, chiefly attended by the opponents of the scheme, very many of its advocates failing to attend from a belief that amalgamation was a foregone conclusion.

There is no doubt that the majority of those who favoured union will, like myself, still stick to the Medical Society, but there can hardly fail to be a serious falling off in the number of new members, since the Royal Society is able to offer so much more to its Fellows, while the Medical Society can offer little if anything which cannot be obtained by the Fellows of the amalgamated societies.

I would therefore suggest that the matter should be reconsidered while this can be done without loss of dignity, and that no pains should be spared to ascertain the opinion of the whole of the Fellows of the society, and I hope that other Fellows of the society will publish their views on this question. I am, Sir, yours faithfully,

Buxton, May 3rd, 1908. CHARLES W. BUCKLEY.

A NOTE ON THE TREATMENT OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—No remedy is more sorely needed than one which will relieve the distressing condition of heart paralysis in diphtheria. Several years ago Dr. J. D. Rolleston[1] warmly recommended adrenalin in this affection, and Dr. F. G. Crookshank has found occasion in your issue of April 25th to reaffirm his own convictions as to the great benefit of this treatment. In view of the importance of the question at issue it would not be right to allow these statements to pass without a thoroughly critical examination of the remedy suggested.

In the first place Rolleston's observations on the prophylactic and stimulant effect of the drug must have been received with some surprise, since the method of administration was by the mouth, and it is generally understood that by this channel the drug is practically inert, being either altered or unabsorbed. Dixon[2] found that, given by the mouth, adrenalin had no effect upon the blood pressure, even after the administration of one drachm—six times the maximum dose recommended. From experimental evidence, then, it seems most unlikely that any effect whatsoever is produced. Practically, I have given the drug a very fair test. In the course of a close study of the heart complications in more than 500 cases of diphtheria at Nottingham I had occasion to test the effect of adrenalin and several other cardiac tonics. Rolleston's directions were faithfully followed but nothing but negative results were obtained, the disease always pursuing its normal course, sometimes with bradycardia and low blood pressure and sometimes ending in collapse. It was evident, however, that the rise in blood pressure and pulse-rate that regularly occurs after the first week or so in hospital might easily be wrongly attributed to the effect of some cardiac tonic. I am aware, however, that Dr. Crookshank, while endorsing Dr. Rolleston's results, prefers hypodermic injections, combining the adrenalin with a little strychnine. But again we have the testimony of Dixon,[3] Janeway, Elliott, and others that the action of adrenalin injected subcutaneously is purely local, except in very large doses. Upon these two suggested improvements in his methods we might justifiably turn some soundly practical but drastic criticisms employed by Rolleston[4] himself in a similar connexion. Of the frequent hypodermic injection he hints that it is an "unjustifiable annoyance, since it interferes with the euthanasia which it is our duty to promote." And of strychnine—that "you might as well paint the bed with it!" I might continue in the same happy vein and say of adrenalin something about its perfect harmlessness as a beverage.

As regards early heart paralysis and the inutility of cardiac stimulants it must be remembered that "cardiac depression" is a very misleading term to apply to this condition. It is not depression but actual *destruction* of tissue from which the heart suffers. This destruction is apparently progressive, as in other diphtheritic paralyses, and reaches its acme about the ninth or tenth day, as evidenced by appearances post mortem and by the fact that at this time the blood pressure and pulse-rate both reach their lowest points and the greatest number of deaths occur. All depressing toxic substances are presumably long since neutralised. I have little doubt from a keen study of these phenomena that the bradycardia of this period is Nature's rest-cure and, moreover, a contrivance for eking out the energies of the heart wall lest they should be spent before this danger-point is

passed by and the processes of repair set in. Flogging on the heart by stimulants, when practically nothing remains to stimulate, can only prematurely deplete its energies; stimulants call forth but do not add to the energies of an organ. For my own part, after witnessing the uselessness of strychnine and other stimulants in several hundred cases, I have treated nearly 400 cases completely without these drugs and my results will compare favourably with any I have seen published. Unless a remedy can be found that will replace destroyed tissue cells with new ones it seems likely that the quest of a remedy for these cases will ever remain a hopeless one.

I am, Sir, yours faithfully,
OWEN H. PETERS, M.D., Ch.B. Melb., D.P.H. Lond.

FIFTY CASES OF SPINAL ANALGESIA.

To the Editor of THE LANCET.

SIR,—In my article upon Fifty Cases of Spinal Analgesia appearing in your issue of April 11th I made the statement that M. Billon had ceased to manufacture the stovaine solution himself and had handed over the work to a firm in Paris. This statement, which was offered as a possible explanation of what I supposed to be a certain feebleness in the analgesia resulting from the use of a second consignment of the solution from Paris, was made on the strength of what I believed at that time to have been reliable information. It gives me much pleasure to be able to contradict both statement and supposition. M. Billon, who has been courtesy itself in affording me assistance and in placing samples at my disposal, writes to me to say that not only has he never dissociated himself from the work but that he has been, since the beginning of 1907, director of the chemical laboratories of Messrs. Poullenc Frères in Paris, where the manufacture of the solution is entirely under his immediate direction and control. With regard to the supposed difference in strength of the solution above mentioned, I am satisfied by extended experience of the method that this supposition was an entirely mistaken one, and that it was partly due to faulty technique on my part, and partly to the fact that some patients are less susceptible to the drug than others and require a slightly larger dose.

I therefore hasten to offer an apology to M. Billon and beg you, Sir, to give early publicity to it, as I fear that my statement may quite unintentionally have produced a wrong impression and one which might prove detrimental not only to M. Billon himself but to the firm of Poullenc Frères.

I am, Sir, yours faithfully,
Mansfield-street, W., May 2nd, 1903. LAWRIE MCGAVIN.

DEATHS DURING ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—I have been deeply interested in the discussions that have recently appeared in THE LANCET on the subject of chloroform administration. In the letters that have been published many have expressed opinions more or less strongly on the cause of death from chloroform anæsthesia; a smaller number have given the bald details of how they themselves administer it, but no one, so far as I have noticed, has attempted to define or to criticise the underlying principles connected with the various practical methods of its administration. Now, these principles are of the utmost value for comparing the various methods and for devising new and safer methods, and I think that the statements given below must be productive, by means of the discussion I hope they will arouse, of some advance in our knowledge of practical chloroform administration.

The first method which I wish to criticise is one in common use and goes under the name of the "graduated series of drops" system. In this system one drop of chloroform to begin with is put on a piece of lint; after a few seconds two drops are added, then three drops, and so on till a maximum number of drops is reached. It is also recommended that after a short time the lint be allowed to rest lightly on the patient's face. The object is, of course, to begin with a very small dose and gradually increase it to a maximum. At first sight this appears quite rational, but I am convinced that the underlying principle is quite wrong. It is founded on the belief that you can talk of the dose of chloroform in the same practical sense that you can talk of the dose of digitalis or hydrocyanic acid. 15 minims of the tincture of digitalis will have the same effect on the heart, whether it be given in a teaspoonful of water or in a pint, but this is not the case with chloroform administered by inhalation. It is common knowledge that if chloroform be given in concentrated vapour it is much more dangerous than if given largely diluted with air. One drachm administered by one person may produce a fatal result in the same time that one ounce administered by another person does. I am quite aware that if this be reasoned out it will amount to a question of dosage, yet practically it is extremely misleading, especially to students and lay people such as coroners and their juries. The only justifiable term to use is percentage or concentration. Now to return to this graduated drop method, as we are told that after a few minutes the lint may be allowed to rest lightly on the face the system practically amounts to this, that the means of dilution of the chloroform is to remain the same throughout the administration, while the amount of chloroform is to be increased. It is important to grasp this as the principle is exactly the opposite of that in the next method to be described. Now if anyone will take the trouble to try this method on himself he will find that with the lint so close to his face it is almost impossible to get anything but a concentrated vapour even though only a couple of drops are put on the lint, and I am sure this will be greatly to the detriment of the patient's safety.

The other method is one I may say that is used in Edinburgh. The great underlying principle in this method is that the amount of chloroform used remains uniformly the same throughout the administration. Thus an equal amount of chloroform—say, half a drachm—is put on the mask at equal intervals, say, one minute. The varying percentage of chloroform vapour required for the case is got by altering the distance of the mask from the face (from two inches or more to half an inch). This method is the one that seems to me by far the safest, for one has only to try it on oneself with a Schimmelbusch's mask to be convinced that one can adjust the percentage of chloroform vapour inhaled much more accurately than one can by the graduated drop method. This method has been accused, especially by the advocates of the drop method, of being unscientific, but I am sure the above remarks will show that it is essentially scientific and a method thoroughly to be recommended.

I am, Sir, yours faithfully,
April 30th, 1908. M.B. EDIN.

DIRECT MEDICATION OF INTESTINES.

To the Editor of THE LANCET.

SIR,—Metchnikoff's contention that most of the diseases which afflict the human family may be ascribed to the bacterial flora of the large intestine is coming to be considered plausible. Autotoxæmia due to the presence of bacteria in the colon, "that clumsy effort of the evolutionary process," is probably far more common than is generally supposed. The Russian biologist believes that a future age will be able to remedy by surgical procedure the imperfect attempt of nature to provide an efficient *cloaca maxima* for man. Meanwhile intestinal germicides and disinfectants offer a reasonable means of combating some of the evils caused by the parasites in our system. For direct medication of the intestines keratine has long been used to enwrap drugs intended to pass through the stomach unaffected by its acid secretions, but readily soluble in the alkaline juices of the bowels. In the treatment of a case of mucoid colitis I have lately prescribed salol in five grain doses inclosed in membranous envelopes. A great improvement was quickly noticed in the condition of the patient, due, I believe, to the action of the phenol liberated by the disintegration of the salol in the intestines. In my opinion very good results are to be expected in this comparatively fresh field of therapeutics. It would be interesting to experiment systematically with lactic acid as an intestinal germicide.

I am, Sir, yours faithfully,
April 17th, 1903. M.D.

MEDICAL DEFENCE UNION.—The annual general meeting of the Medical Defence Union will be held on May 21st at the Medical Institution, Hope-street, Mount Pleasant, Liverpool, at 4.30 P.M. The annual report of the council, together with the balance-sheet and accounts as certified by the auditors, will be presented to the members and the usual statutory business as required by the articles of association carried out.

THE TWENTY-FIFTH CONGRESS OF INTERNAL MEDICINE.

(FROM OUR VIENNA CORRESPONDENT.)

THE Twenty-fifth Congress of Internal Medicine was opened on April 6th in the large Hall of Ceremonies of the University of Vienna. This was the second meeting of this Congress in Vienna. The first occasion was in 1890, when Professor Billroth and Professor Nothnagel were present, and the words of the former with which he opened the proceedings are true for all time: "Science has but one object—truth combined with clarity; and the duty of the medical practitioner is to apply this combination to the welfare of humanity." The opening scene of the Congress presented an impressive spectacle, and all the meetings, which were continued from April 6th to 10th, were a conspicuous success. Medical and scientific men from all German-speaking countries had assembled to discuss questions of professional interest, a few of the better-known German visitors being Dr. Leube (Würzburg), Dr. Penzoldt (Erlangen), Dr. Stintzing (Jena), Dr. Quincke (Kiel), Dr. Pfeiffer (Wiesbaden), Dr. Hering (Prague), Dr. Lenhartz (Hamburg), Dr. Schwalbe (Berlin), and Dr. Krehl (Heidelberg). The visitors from other countries included Professor William Osler (Oxford), Dr. A. S. F. Grünbaum (Leeds), Dr. Pratt (Boston, U.S.A.), Dr. Poehl (St. Petersburg), and Dr. Turban (Davos). Naturally enough, all the professors of the Vienna Medical Faculty were present and took an active part in the work of the Congress. One of the accessories was an exhibition of objects of medical interest arranged by Professor Schlesinger. The Minister of Education welcomed the Congress on behalf of the Government. After the PRESIDENT, Professor Müller (Munich), had opened the Congress the MINISTER addressed the members, of whom about 500 were present. He said that the Government paid the closest attention to medical matters and he wished the members of the Congress to visit the newly opened clinics in order to satisfy themselves that Vienna was not behind other cities in providing adequate opportunities for medical study. The high position which the Vienna Medical School has hitherto occupied would be certainly maintained now that the old General Hospital was replaced by a modern building and that men of eminence had so many inducements to take up their abode in Vienna. The bürgermeister (mayor) then spoke some words of welcome and invited all the members of the Congress to a banquet given by the city in their honour. The last official speech was delivered by Dr. URIEL, general staff surgeon, who in the name of the Minister of War wished the Congress every success. He said that the Army Medical Corps had been watching with the utmost interest the progress which had been made in practical and scientific medicine during the past few years. The increased knowledge of prophylaxis had caused a revolution in the methods of military sanitation and their application in future wars would result in a great reduction of the mortality incidental to campaigning. The Congress then proceeded to practical work, commencing with the official subjects of discussion.

The Relation of the Female Sexual Organs to Internal Diseases.

After a short address by the PRESIDENT on Specialism in Internal Medicine a discussion on the Relations of the Female Sexual Organs to Internal Diseases was opened by Professor ROSTHORN (formerly of Heidelberg but now of Vienna) and Professor LENHARTZ. The first-named speaker confined himself entirely to anatomical details, only referring to well-known conditions, but his lucid exposition touching on a number of interesting points, principally on the relations of pregnancy to cardio-vascular and renal diseases, was well received by his hearers. Professor Lenhartz, who was the next speaker ("co-referent"), dealt especially with the treatment of gynæcological affections in their relation to internal diseases. He strongly condemned the methods of some surgeons who performed operations which might be avoided; he asserted that in this particular all the eminent gynæcologists were of the same opinion as himself and he added that "polypragmasia" was only too well known in large cities. He maintained that in the majority of cases disorders of the sexual organs were not the cause but symptoms of grave nervous debility, and required not local treatment by a specialist but the use of tonics and measures likely to increase the strength. Symptoms suggesting hysteria or neurasthenia should be carefully analysed before resorting to the knife.

Dr. PLOENIES (Dresden) read a paper on the Relation between Menstruation and Diseases of the Stomach. He had observed that sometimes copious bleeding from the stomach—true hæmatemesis—occurred before and after the regular flow of the menses, and he attributed it to hypertonus of the blood-vessels regulated by the splanchnic and hypogastric plexuses. Diseases of the stomach, such as dilatation, hyperacidity, and nervous irritability, were often increased just before the appearance of the menses. Other observers had seen febrile icterus preceding the menstrual flow by six or eight days.

Dr. TUSZKAI (Marienbad) read a paper on the Relation between Pregnancy and Heart Disease. He said that whilst menstruation in a patient suffering from heart disease was often postponed and belated in the first instance the quantity was increased, and sometimes copious menstruation acted as a safety valve like venesection. The progress of pregnancy in such women was dependent on the degree of compensation and the prognosis was not so bad as was formerly believed. Even five or six labours might occur without the patient breaking down, provided that labour was not too difficult. Where this was to be feared premature labour must be induced before the fœtus had grown too large.

Dr. TURBAN read a paper on the Relation between Pregnancy and Pulmonary Tuberculosis. He said that tuberculosis was prejudicially affected by pregnancy and when the disease had attacked the lungs and was in an advanced stage the puerperium was a source of danger. If a child was born it should not be suckled by the mother. This, however, was not necessary in the case of thin women who were anæmic without being tuberculous.

Some papers on the Appearance of Albumin during Menstruation and of Graves's Disease complicating Gravidity were read but they were of minor importance.

In the afternoon the discussion was continued. Dr. HOFBAUER (Vienna) read a paper on Sexual Asthma. He said that, notwithstanding the absence of the crystals and of bronchitic symptoms, the aggregation of symptoms must be called asthma on account of the changes of the elasticity of the lungs. Acute emphysema had been noticed, caused by increase of the inspiratory volume of air due to lessened contraction of the diaphragm, which was under the influence of the cortex of the brain. X-ray examination was useful in the investigation of these cases.

Dr. SINGER (Vienna) read a paper on Climacteric Diseases of the Bowel. He said that according to his observations in cases of early cessation of the menses, such as at the age of 35 or 40 years, meteorismus was likely to appear, which two symptoms together might cause an erroneous diagnosis of pregnancy to be made. Hæmorrhages from the intestines also appeared sometimes at the climacteric; they were caused by small erosions or ulcerations, mostly situated at the sigmoid flexure which was very often compressed by fæcal accumulations, owing to diminution of the contractile power of the muscular coats of the intestine. These hæmorrhages might lead to a mistaken diagnosis of tumour, but appropriate treatment such as massage, electricity, and aperients would bring about recovery in a few weeks.

On the evening of the first day the members of the Congress were entertained at a banquet provided by the city of Vienna in the Rathhaus which is a magnificent Gothic building. The fine Festsaal or Hall of Ceremonies, one of the largest in Europe, with its 2000 electric lights, presented a splendid spectacle. The company numbered upwards of 500, since many of the medical men had brought their ladies. The bürgermeister, who is himself under medical treatment on account of diabetes with ocular complications, welcomed the guests in a humorous speech, wishing them all success in their endeavours to elucidate the cause of diseases and their treatment for the benefit of all sufferers, himself included. Several toasts were drunk in honour of the Emperor, the Government, and some eminent physicians.

The second day was chiefly occupied, first, by the reading of a paper on

The Present Position of the Pathology and Treatment of Syphilis,

by Professor NEISSER (Breslau), and, secondly, by the ensuing discussion. Professor Neisser said that three important advances had been made by science in the recognition of the nature of this disease—namely, Schaudinn's discovery of the spirochæta pallida as the cause of syphilis, which was now accepted as proved;

Metchnikoff's discovery that apes could be infected with this micro-organism; and Wassermann's discovery that the blood serum of syphilitic persons had a specific reaction. The essential character of syphilis always remained the same and there was no qualitative difference between slight and severe manifestations of the infection. The modern idea was to make a correct diagnosis as early as possible and to begin treatment at the very first opportunity. Intermittent treatment was not advisable. Animals infected with syphilis and treated after seven days with injections of atoxyl might escape infection on account of the spirochæta being killed before the disease had spread in the body. Atoxyl was the best remedy, at least in the lower animals. It must, however, be employed cautiously in men, for blindness has been caused more than once by it. Mercury, iodine, and quinine were also very useful. Patients should be treated with as much mercury as they could tolerate, for the spirochæta could, and must, be killed in the tissues. The expectation of an effective serum treatment of syphilis had not hitherto been realised, but Professor Neisser was convinced that such a method would in time be discovered and that then nothing but the initial stages of syphilis would be seen by medical men, as the later stages would disappear under the new treatment.

An animated discussion ensued on the merits of Wassermann's reaction.

Dr. SALOMON believed that only very pronounced reactions were convincing, because slight or medium results might be obtained in persons suffering only from tumours or tuberculosis.

Dr. SPIEGLER (Vienna) said that he had examined the chemical constitution of syphilitic blood and had found that the proportion of the albuminoid bodies of the serum was variable, whilst in normal blood serum the proportion was always the same.

Professor ZINGER (Vienna) spoke on the inoculation of apes with syphilis. He said that successful inoculations were now the rule and the initial lesions were very similar to those found in the human infection.

Dr. CITRON (Berlin) and Dr. LENZMANN (Duisburg) had had similar experiences.

In the afternoon Dr. HERZ (Vienna) read a paper on

Certain Heart Diseases

the cause of which was found in insufficiency of the space at the disposal of the expanding and contracting heart, especially through the person sitting in a faulty position when engaged in writing, drawing, or other sedentary work. Dentists were often victims to this kind of heart disease from the constantly bent position of the upper part of the body. The action of the heart was insufficient, not from weakness, but because the muscle could not exert its full power owing to its being hemmed in. Diseases of the stomach and the intestinal canal could by pushing the diaphragm up produce a diminished working space for the heart.

Professor EHRMANN (Potsdam) read a paper on the Correlation between Glandular Organs and other Parts of the Body. He has found that the internal secretion of the thyroid and the sexual glands was influenced by the nervous emotions, but, on the other hand, they influenced the nerves as well.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE summer term commenced on April 22nd and at once both the old and the new university buildings were overflowing with active and earnest life, for the summer term brings to a head the work of the year and the culmination is reached when the examinations begin in June; in other words, the time available for the completion of the work which must precede the examinations varies from seven weeks in the cases of some of the arts and science subjects to eight or nine weeks in the medical subjects. With the point of their endeavour so nearly before them the students throw more energy into their work than in the two previous terms and thus the summer term is the most interesting term of the year. In addition to the ordinary class work necessary for admission to examinations Professor T. Turner is to deliver a series of lectures on Metals and Alloys, which are open to the general public, and the Ingleby lectures, which are open to all members of the medical profession, will be delivered on Thursdays, May 7th and 14th, by Mr. Christopher Martin who has chosen as his subject Myoma of the Uterus. A very important change has recently been made in those regulations of the University which deal with the admission of graduates of other universities to the Master's degree. Hitherto a course of two years of study has been demanded from such graduates before they were admissible to the examinations for the Master's degree but the new regulation reduces the period of study to one year. The change has been made with the object of encouraging intercourse between the various universities and with the hope that graduates of other universities may be induced to make use of the unrivalled advantages which can be obtained in Birmingham. It should be clearly understood, however, that the reduction of the period during which the studies must be carried out in Birmingham in no way diminishes the high standard which the candidates have to attain before they are admissible to the Master's degree.

The Birmingham Sanatorium for Consumptives.

At the inquiry concerning the application of the corporation for powers to borrow £8500 for the purpose of erecting a sanatorium at Leckhampton, which was held on Friday last, it was pointed out to the Local Government Board inspector, Dr. H. Timbrell Bulstrode, that it was intended to provide accommodation for 40 patients, and that it was important that the buildings should be finished during the summer so that they might be available for use next winter. Evidence was produced to show that an ample water-supply was available, that the buildings would be practically fireproof, that the sewage would be dealt with by the septic system, and that the effluent would be discharged on to suitable land. So far as the staff is concerned it was stated that, in the first instance, it was the intention of the council to appoint a medical superintendent, a matron, and two nurses, but if this staff proved to be inadequate it would be increased.

The Stamping-out of Glanders.

On Jan. 1st, 1908, the Glanders and Farcy Order came into operation. The Order makes it compulsory for local authorities to destroy all horses, asses, or mules affected with glanders or farcy and to pay compensation out of the local rates. The minimum amount of compensation payable for a clinically diseased animal is £2 for each horse and 10*s.* for each ass or mule, and if the amount of compensation exceeds the minimum it is not to exceed one-fourth of the value of the animal before it became diseased. All horses, asses, or mules believed to have been in contact with diseased animals are to be subjected to the mallein test and those which react in such a manner as to suggest that they are affected are to be slaughtered. When the post-mortem examination shows that the animal was affected the compensation to be paid is to be one-half of the value of the animal immediately before it was tested, but not exceeding £25 for a horse or £6 for an ass or a mule; but if the post-mortem examination fails to demonstrate the disease full value is to be paid, but not exceeding £50 for a horse and £12 for an ass or a mule. The markets and fairs committee reports that the cost falling upon the city under this Order for the period from Jan. 1st to March 31st has been £616 10*s.* The committee expresses its agreement with the Local Government Board regarding the importance of the eradication of the disease and the efficacy of the measures adopted, but considering that the matter is one of national importance it is of the opinion that a substantial part of the cost should have been made a charge upon money provided by Parliament, and it expresses regret that the Government has not sanctioned such a provision. Fortunately Mr. Malcolm, the veterinary inspector, is inclined to think that the worst is over and that the number of cases will be comparatively small in future, and if his prediction is verified it may be considered that a very valuable result has been gained at a comparatively slight cost.

Scarlet Fever in West Bromwich Workhouse.

The West Bromwich board of guardians have very wisely decided to suspend visiting until further notice. The reason for this decision is that scarlet fever has been introduced into the workhouse, apparently by visitors; at least that is the master's opinion, which he justifies by the fact that at the very outset of the outbreak a child was attacked who had

THE TWENTY-FIFTH CONGRESS OF INTERNAL MEDICINE.

(FROM OUR VIENNA CORRESPONDENT.)

THE Twenty-fifth Congress of Internal Medicine was opened on April 6th in the large Hall of Ceremonies of the University of Vienna. This was the second meeting of this Congress in Vienna. The first occasion was in 1890, when Professor Billroth and Professor Nothnagel were present, and the words of the former with which he opened the proceedings are true for all time: "Science has but one object—truth combined with clarity; and the duty of the medical practitioner is to apply this combination to the welfare of humanity." The opening scene of the Congress presented an impressive spectacle, and all the meetings, which were continued from April 6th to 10th, were a conspicuous success. Medical and scientific men from all German-speaking countries had assembled to discuss questions of professional interest, a few of the better-known German visitors being Dr. Leube (Würzburg), Dr. Penzoldt (Erlangen), Dr. Stintzing (Jena), Dr. Quincke (Kiel), Dr. Pfeiffer (Wiesbaden), Dr. Hering (Prague), Dr. Lenhartz (Hamburg), Dr. Schwalbe (Berlin), and Dr. Krehl (Heidelberg). The visitors from other countries included Professor William Osler (Oxford), Dr. A. S. F. Grünbaum (Leeds), Dr. Pratt (Boston, U.S.A.), Dr. Poehl (St. Petersburg), and Dr. Turban (Davos). Naturally enough, all the professors of the Vienna Medical Faculty were present and took an active part in the work of the Congress. One of the accessories was an exhibition of objects of medical interest arranged by Professor Schlesinger. The Minister of Education welcomed the Congress on behalf of the Government. After the PRESIDENT, Professor Müller (Munich), had opened the Congress the MINISTER addressed the members, of whom about 500 were present. He said that the Government paid the closest attention to medical matters and he wished the members of the Congress to visit the newly opened clinics in order to satisfy themselves that Vienna was not behind other cities in providing adequate opportunities for medical study. The high position which the Vienna Medical School has hitherto occupied would be certainly maintained now that the old General Hospital was replaced by a modern building and that men of eminence had so many inducements to take up their abode in Vienna. The bürgermeister (mayor) then spoke some words of welcome and invited all the members of the Congress to a banquet given by the city in their honour. The last official speech was delivered by Dr. URIEL, general staff surgeon, who in the name of the Minister of War wished the Congress every success. He said that the Army Medical Corps had been watching with the utmost interest the progress which had been made in practical and scientific medicine during the past few years. The increased knowledge of prophylaxis had caused a revolution in the methods of military sanitation and their application in future wars would result in a great reduction of the mortality incidental to campaigning. The Congress then proceeded to practical work, commencing with the official subjects of discussion.

The Relation of the Female Sexual Organs to Internal Diseases.

After a short address by the PRESIDENT on Specialism in Internal Medicine a discussion on the Relations of the Female Sexual Organs to Internal Diseases was opened by Professor ROSTHORN (formerly of Heidelberg but now of Vienna) and Professor LENHARTZ. The first-named speaker confined himself entirely to anatomical details, only referring to well-known conditions, but his lucid exposition touching on a number of interesting points, principally on the relations of pregnancy to cardio-vascular and renal diseases, was well received by his hearers. Professor Lenhartz, who was the next speaker ("co-referent"), dealt especially with the treatment of gynæcological affections in their relation to internal diseases. The progress of pregnancy in such women was dependent on the degree of compensation and the prognosis was not so bad as was formerly believed. Even five or six labours might occur without the patient breaking down, provided that labour was not too difficult. Where this was to be feared premature labour must be induced before the fœtus had grown too large.

Dr. TURBAN read a paper on the Relation between Pregnancy and Pulmonary Tuberculosis. He said that tuberculosis was prejudicially affected by pregnancy and when the disease had attacked the lungs and was in an advanced stage the puerperium was a source of danger. If a child was born it should not be suckled by the mother. This, however, was not necessary in the case of thin women who were anæmic without being tuberculous.

Some papers on the Appearance of Albumin during Menstruation and of Graves's Disease complicating Gravidity were read but they were of minor importance.

In the afternoon the discussion was continued. Dr. HOFBAUER (Vienna) read a paper on Sexual Asthma. He said that, notwithstanding the absence of the crystals and of bronchitic symptoms, the aggregation of symptoms must be called asthma on account of the changes of the elasticity of the lungs. Acute emphysema had been noticed, caused by increase of the inspiratory volume of air due to lessened contraction of the diaphragm, which was under the influence of the cortex of the brain. X ray examination was useful in the investigation of these cases.

Dr. SINGER (Vienna) read a paper on Climacteric Diseases of the Bowel. He said that according to his observations in cases of early cessation of the menses, such as at the age of 35 or 40 years, meteorismus was likely to appear, which two symptoms together might cause an erroneous diagnosis of pregnancy to be made. Hæmorrhages from the intestines also appeared sometimes at the climacteric; they were caused by small erosions or ulcerations, mostly situated at the sigmoid flexure which was very often compressed by fæcal accumulations, owing to diminution of the contractile power of the muscular coats of the intestine. These hæmorrhages might lead to a mistaken diagnosis of tumour, but appropriate treatment such as massage, electricity, and aperients would bring about recovery in a few weeks.

On the evening of the first day the members of the Congress were entertained at a banquet provided by the city of Vienna in the Rathhaus which is a magnificent Gothic building. The fine Festsaal or Hall of Ceremonies, one of the largest in Europe, with its 2000 electric lights, presented a splendid spectacle. The company numbered upwards of 500, since many of the medical men had brought their ladies. The bürgermeister, who is himself under medical treatment on account of diabetes with ocular complications, welcomed the guests in a humorous speech, wishing them all success in their endeavours to elucidate the cause of diseases and their treatment for the benefit of all sufferers, himself included. Several toasts were drunk in honour of the Emperor, the Government, and some eminent physicians.

The second day was chiefly occupied, first, by the reading of a paper on

The Present Position of the Pathology and Treatment of Syphilis,

by Professor NEISSER (Breslau), and, secondly, by the ensuing discussion. Professor Neisser said that three important advances had been made by science in the recognition of the nature of this disease—namely, Schaudinn's discovery of the spirochæta pallida as the cause of syphilis, which was now accepted as proved;

time but of the nine patients discharged two appeared to have recovered completely and four showed signs of great improvement. Mr. Edward Hughes, the medical officer to the institution, appears to be quite satisfied with the results attained in the short period that has elapsed since the first patients were received and in a report to the board of guardians he points out that if these 32 patients had been treated in the ordinary wards of the workhouse infirmary they might have infected other patients who were suffering from curable diseases.

West Wales Sanatorium.

It is satisfactory to find that the Carmarthen county council has at last been prevailed upon to make a contribution towards the West Wales sanatorium for consumptives. Proposals to subscribe towards the erection of the building have on previous occasions been defeated but at a meeting of the council held on April 29th it was unanimously decided to contribute £150 annually on the understanding that two beds should be at the disposal of the county council. It is expected that the institution will be opened during the third week in July. In the previous week the Royal Sanitary Institute will be holding its annual congress in Cardiff and arrangements will no doubt be made for an inspection of the buildings by those attending the meeting whose interests lie in that particular direction.

Medical Inspection of School Children.

At the meeting of the Bristol education committee held on April 30th it was decided to appoint five "part-time" medical officers as inspectors of school children at salaries of £100 per annum, one at least of these officers to be a woman. It is proposed that each officer shall devote to this special work between two and three hours per day for three days of the week. In addition two health visitors, who will be certificated nurses, are to be appointed at annual salaries of £70 each.

The late Mr. David Lloyd.

Mr. David Lloyd died suddenly from heart failure on April 25th at Carmarthen. The deceased, who was 56 years of age, had for many years practised at Newcastle-Emlyn, where he was medical officer of the Newcastle-Emlyn rural district council; he had also recently been appointed medical inspector of schools by the Carmarthenshire county council. In 1897 he was chairman of the Cardiganshire county council and was presented to the late Queen Victoria in that year. He was on the commission of the peace for the county of Cardigan. Mr. Lloyd was highly esteemed at Newcastle-Emlyn and much sympathy is felt for his widow and three children.

May 4th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Alterations in Public Appointments following on Sir Henry D. Littlejohn's Resignation.

Sir Henry D. Littlejohn held the double office of medical officer of health and police surgeon to the city of Edinburgh. It has been wisely decided to separate these two posts for the future. The medical officer of health will in future confine himself to the duties of that office, excepting in so far as he has direct sanction to go beyond them. This reservation is desirable in Edinburgh for the medical officer of health of the city might very suitably be a lecturer in the Extra-Mural School. As regards the police surgeoncy the city is to be divided into four districts with a police surgeon in each, while the professor of medical jurisprudence is officially associated with the work and granted an honorarium of £100 per annum. There are already many applicants for the police appointments.

Death of Miss Spencer, late Lady Superintendent of Nurses, Royal Infirmary, Edinburgh.

During the spring vacation not only has the Royal College of Physicians lost its President by death but the lady who so long occupied the responsible post of lady superintendent of nurses in the Royal Infirmary, Edinburgh, has also died. It is only about a year ago that she resigned her position in the Royal Infirmary and had retired to Dollar with the prospect of years of quiet and rest in front of her. She, however, was seized with acute illness and although at one time it was thought that she would recover symptoms recurred and in spite of all that was done for her she died. The Royal Infirmary, the medical staff of the infirmary, and other bodies were represented at the funeral.

Glasgow Maternity and Women's Hospital.

The new buildings of the Maternity and Women's Hospital, Glasgow, were opened last week by the Duchess of Montrose. Since 1834, when the hospital was started on a very modest scale, the claims upon the services of the institution have steadily increased. The increase of total cases indoor and outdoor from 934 in 1880 and 1283 in 1890 to 3749 in 1907 gives an indication of the need that existed for an increase of accommodation for the sake of patients and students alike. So far as can be seen there is now no fear of the hospital proving inadequate for years to come. The new building forms an imposing pile at the top of Montrose-street. The steep gradient on which the foundations are laid presented some difficulties to the architect but by skilful planning the peculiarities of the situation have been turned to advantage. The hospital provides accommodation for 108 patients (92 in the general maternity department and 16 in the isolation block). The importance of having a special department for the treatment of cases which might from their character be harmful to other patients in the ordinary maternity wards has long been recognised in the best equipped institutions of the kind. The building is arranged in such a way that the wards receive the maximum of sunlight and air. The accommodation in each ward ranges from one to eight beds. The wards are bright and cheerful and each one is provided with radiators, a number of them having also an ordinary fireplace. On the first floor are two large labour rooms, one containing four and the other two beds. These apartments have a splendid north-west light, the walls are tiled to the ceiling, and the floors are constructed of terrazo, so that the whole interior can be flushed with a hose-pipe. Adjoining the labour rooms, which are equipped on the lines of a modern operating theatre, are a sterilising room, a lavatory, a robing room for the staff, a waiting room for the students, and a duty room for the sister in charge. As one of the leading functions of the new hospital will be the training of students no pains have been spared to provide a complete and up-to-date school for the teaching of practical obstetrics and gynæcology. There is a large lecture theatre occupying two storeys and giving accommodation for 90 students. In addition, on the top flat there is a large operating theatre with accommodation for 60 students. The whole gallery here is formed of terrazo, the walls also are tiled in their whole extent, so that the interior can be kept scrupulously clean. Together with the site for the hospital the directors acquired a property which is to be used as a residence for students who will thus be within immediate call when their services are required. Formerly maternity students had to find accommodation anywhere in the neighbourhood of the hospital. This new arrangement, coupled with the splendid advantages for acquiring a thorough training in the institution, should prove very acceptable and be a valuable adjunct to the teaching of medicine in Glasgow. In the hospital also a special room has been provided for the bathing of babies, the floor being formed of terrazo and the walls being tiled. Sleeping accommodation is provided also for 44 nurses in the hospital. Special attention has been directed to the laundry arrangements, all the linen from the isolation block passing through a special washhouse where it is first steeped in a disinfectant and then boiled before being sent to the ordinary washhouses. The mortuary is detached from the hospital and there are also provided a well-equipped research laboratory and private investigation room. There is no doubt that this hospital is now the most perfect of its kind in the country and this is largely due to the fact that before the plans were completed two of the visiting members of the staff, accompanied by Dr. D. J. Mackintosh as consulting expert, were requested by the board of directors to visit the leading hospitals at home and on the continent, and as a result all the leading improvements at home and abroad have been embodied in the Glasgow hospital.

Honour to a Glasgow Surgeon.

His Majesty the King of Italy has been pleased to confer upon Dr. Thomas Reid of Glasgow the high order "Commendatore of the Crown of Italy." This distinction is designed as a recognition of Dr. Reid's high merit as an ophthalmic surgeon and also of his many and valued services to the clinique of ophthalmology in the University of Turin, where his intimate friend Professor Reymond is chief. Dr. Reid joined the staff of the Glasgow Eye Infirmary in 1868 never been outside the workhouse for three and a half years. Whether the disease was introduced by visitors or not the decision to prohibit visiting whilst it exists is a wise precaution which cannot be the cause of any great hardship either to inmates or to visitors.

The Walsall and District Hospital.

The efficiency of any hospital depends very largely upon the amount of its income, and that being so the alarm of the treasurer of the Walsall and District Hospital at the result of the last quarter's work can easily be understood. The income of the hospital for the quarter was £452, the expenditure was £1197, and the adverse balance had increased to £1604, or £900 more than 12 months ago. It is true, as the chairman pointed out, that the hospital possesses a reserve fund of £20,000, but it is obvious that a considerably increased annual income is necessary or the reserve fund will have to be drawn upon heavily if the work of the institution is to proceed in a satisfactory manner. In the circumstances the decision to appoint a committee to canvass the town and district for subscriptions is wise and it has not been arrived at too soon.

The Health of the City.

The health of the city has improved rapidly during the past two weeks and the death-rate has fallen from 18·3 to 15·9 per 1000. The epidemic of influenza is becoming both less prevalent and less virulent. Scarlet fever, measles, and diphtheria are on the wane and there are hopes that with improving weather we may look forward to more normal conditions of health. The epidemic of scarlet fever reached its height in November last, when the medical officer's report stated that the disease was "more prevalent than at any period during the last five or six years." After Nov. 26th the decline commenced and with a few occasional exacerbations it has continued. 81 cases had been notified in the week preceding Nov. 26th and there were then 602 cases in the scarlet fever hospital. By the end of January the number of cases in the hospital had fallen to 502; at the end of February to 455; at the end of March there were 428 cases, and on Saturday last the number of cases in hospital had decreased to 403, whilst during the week only 39 cases had been reported. We shall probably now pass into a period of comparative immunity but unless some new and important discovery is made in association with the means by which the disease is spread the period of immunity will be followed sooner or later by another epidemic.

The Health of King's Norton.

From the yearly report of Dr. Reginald Green, the medical officer of health of the King's Norton and Northfield urban districts, it appears that during the year 1907 the birth-rate of the districts decreased 1·15 per 1000 as compared with the previous year, and the general death-rate increased from 9·97 to 10·78 per 1000. The infant mortality rate was 105 per 1000, the same as in the preceding five years. The increase in the general mortality rate does not seem to be ascribable to any special cause and apparently any efforts which may have been made to reduce the infantile mortality have been ineffective.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

Appointment of Dr. G. R. Murray to the Chair of Systematic Medicine in the Victoria University of Manchester.

THE profession in Newcastle and neighbourhood will deeply regret the loss of Dr. George Redmayne Murray who has accepted the invitation of the council of the Victoria University of Manchester to become the professor of systematic medicine in that University and, *ex-officio*, full physician to the Royal Infirmary at Manchester. The University of Manchester is heartily to be congratulated upon having secured the services of Dr. Murray and the latter is to be congratulated equally heartily upon having been invited to fill this important and interesting position—the invitation itself being a well-deserved tribute to his work in the past. It is understood that as the new infirmary buildings in Manchester will not be opened until October Dr. Murray will not sever his connexion with the Royal Victoria Infirmary and College of Medicine in Newcastle until towards the end of September.

The Arrangement in Manchester between the University and the Infirmary with Regard to the Chairs of Systematic Medicine and Surgery.

The arrangement which exists in Manchester between the authorities of the University and the authorities of the infirmary, by which the professor of systematic medicine and the professor of systematic surgery are *ex-officio* full physician and full surgeon respectively to the infirmary, is one which might be considered with advantage by other provincial universities when considering any future re-organisation schemes. In Manchester a regulation is in existence under the provisions of which a physician or a surgeon to the infirmary on attaining the age of 60 years retires from his appointment, and this regulation is also applicable to the physician or surgeon who holds the chair of systematic medicine or systematic surgery—on retiring from the infirmary he retires also from his professorship. In this way a very close connexion is maintained between the university and the infirmary in Manchester, which must be of the greatest benefit to both institutions. An age limit also allows of the introduction of younger men more frequently than when no age limit exists, and as in most, if not in all, places an age limit exists for members of the staffs of the various hospitals it follows that unless both appointments are laid down together the teaching will, or at least may, be continued by a man who has retired from the more active and practical part of his work, and this for obvious reasons is not in the best interest of the student, for whose benefit, after all, all professorships exist. In most other subjects an age limit for retirement is not yet possible on financial grounds. But in the case of professors of medicine and surgery the holders of these appointments are the leaders of the profession and the income which they enjoy from private practice should allow of provision being made for the time when they will have retired, which is not the case in many of the subjects of the medical curriculum, where the head of the department is paid a comparatively small fixed salary which in most cases is barely more than enough to pay his expenses. But though an age limit for retirement may not be possible in, for instance, the subject of pathology, the argument for the arrangement whereby the head of the department of pathology in the school shall also be *ex-officio* head of the same department in the infirmary is just as strong as, if not stronger than, in the case of surgery and medicine.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Housing in Merthyr.

THE Merthyr corporation is extending its building operations in the direction of erecting 38 workmen's houses at an estimated cost of £7650 upon land which it is proposed to lease at an annual rental of 1½*d.* per square yard. It is intended to charge a weekly rental of 6*s.* for each house. In 1902 the corporation built 100 houses which are now let at about the same rent. In his recently issued annual report the medical officer of health (Dr. Alexander Duncan) states that during 1907 there were 72 houses closed as uninhabitable and 65 others which he reported as being unfit for habitation were put into a proper condition. Although there is some improvement over former years there is still a large amount of overcrowding in the borough but the activity of the council is apparently having a good result. A charge has frequently been made, and has quite recently been repeated, against the owners of houses who are also tradesmen that the tenants are compelled to make weekly purchases at the shops owned by the landlords, and that in default of doing so the tenants are given notice to leave their houses. It is obvious that if such a custom is prevalent it is open to the gravest abuse and steps should be taken to put a stop to it.

Newport Sanatorium for Poor-law Patients.

The sanatorium established, apart from the workhouse, for consumptive patients under the care of the Newport board of guardians has now been occupied about four months. During that period 32 persons have been admitted for treatment, of whom four died and nine have been discharged. A great many of those received had been ill for some considerable before Judge Overend. It was an appeal in which three farmers were fined for refusing to allow samples of milk to be taken for analysis which they were supplying to Tamlaght Coöperative Creamery. The manager of Tamlaght Coöperative Agricultural and Dairy Society was also fined for obstructing the food and drugs inspector in the execution of his duty. It would appear that the farmers refused to give samples and the manager of the creamery directed them not to supply samples. The inspector's case was that the creamery was a coöperative society or limited company and that he was entitled to take the sample to ascertain if proper milk was being supplied. The manager of the creamery contended that the inspector's test would not be a correct one, as the standard of the milk might vary from day to day, whereas he contended the true test was made by taking a composite sample from each supplier's milk daily and by ascertaining the standard of cream at regular intervals. The county court judge upheld the magistrate's decision, being of opinion that it was highly important that milk should be tested and that the State had the right to have it done.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Principal Causes of the Mortality from Diphtheria since the Introduction of Serum-therapy.

ON April 21st M. Martin communicated to the Academy of Medicine a study of 853 cases of diphtheria treated at the Pasteur Hospital by serum-therapy with 83 deaths, this being a mortality of 9·7 per cent., which practically coincides with the published mortality from the disease since the introduction of the treatment. This could be lowered if the injections were given earlier and if in selected cases prophylactic injections were employed. In reviewing the age-incidence of the fatal cases it is seen that they occur chiefly in infants under two years of age, which points to the fact that the treatment is not given early enough owing to the late establishment of the diagnosis. Other cases are accounted for by bacterial complications in secondary cases. The remedy is to be found in the individual isolation of patients. Toxic complications also help to swell the mortality, the disease being cured locally, but grave general symptoms and sequelæ supervening, due to an intense toxic condition which defies the means of defence by damaging the hepatic, renal, and suprarenal functions. To avoid this disaster the serum must be pushed vigorously, as in the treatment of diphtheritic paralyses. By such means the mortality amongst young infants may be lowered.

Sugar Refining as a Dangerous Occupation.

At the Academy of Medicine on April 21st M. Bernheim and M. Dieupart reported their experiences in an "anti-tuberculosis" dispensary situated near a sugar refinery, where they observed 150 cases of tuberculosis amongst 1500 hands employed in the works. Women proved more susceptible than men. They attributed this disproportionate frequency of the disease less to a chemical action of the sugar than to a pneumonokoniosis. The countless tiny sharp fragments of sugar dust in which the refiners are continually smothered reach the bronchi and the alveoli and cause lesions just as if they were particles of metallic dust. The hygienic conditions in these works are faulty and the hands are too badly paid to obtain proper nourishment. Further, the observers found very defective conditions of the teeth in these people, a great number of them being completely toothless; and lastly, the disease ran a very virulent course, advancing rapidly and nearly always to a fatal issue, as occurs when tuberculosis attacks diabetic subjects.

The Therapeutic Uses of Venous and Arterial Hyperæmia.

In M. Tuffier's clinique at the Beaujon Hospital these methods have been given a systematic trial, and M. Durey brought the results before the notice of the Medical Society of Paris on April 25th. By means of 200 cases treated in the course of two years he showed that venous hyperæmia induced by stasis gives excellent results in acute inflammatory conditions, provided Professor Bier's own technique is followed scrupulously; he further showed that arterial hyperæmia is rather of service in chronic or non-infective conditions, that the dangers of its employment are negligible, and that, speaking generally, hyperæmia should be employed less as a therapeutic measure *per se* than as a physiological adjuvant to natural curative processes.

Post-Graduate Medical Teaching.

The practical demonstrations for practitioners, which have been organised by a body of physicians and surgeons on the staffs of the hospitals and by various specialists, will be held in May and June at the Cercle de Luxembourg, 16, Rue de Luxembourg, and in the different hospitals and cliniques. A subscription of 20 francs covers the 21 demonstrations of the course.

Obituary: M. Chamberland.

The world of science in France has suffered severe losses recently and the latest is that of M. Charles Edouard Chamberland, which occurred on May 2nd. He was born in 1851 at Chilly-le-Vignoble, in the Jura. In his early youth he showed a marked aptitude for science and especially for mathematics. In 1857 he left his *école normale*, where he had distinguished himself in his studies and had become an *agrégé-préparateur*, and shortly afterwards he had the good fortune to meet Pasteur. He was an enthusiastic member of that great man's first band of pupils and in a little while proved himself one of his most valued assistants. M. Chamberland was a member of the Academy of Medicine, an Officer of the Legion of Honour, and assistant director of the Pasteur Institute. He made numerous contributions to the Transactions of the Academy of Science, which included a study of anthrax, a paper on its prevention by vaccination based on the researches of Louis Pasteur, and works on drinking-waters in their relation to health and epidemic disorders. M. Chamberland was returned as the Republican radical representative for the Jura at the general elections in 1885; he did not offer himself for re-election in 1889.

May 4th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Mortality from Tuberculosis.

AT a recent meeting of the Berlin Medical Society Professor B. Fraenkel read a paper on the Decrease of the Mortality from Tuberculosis and its Causes. He said that according to the statistical returns there were in Prussia 88,283 deaths from tuberculosis in 1886 and 64,459 in 1906, giving death-rates respectively of 31·14 and 17·26 per 10,000 of the population. The deaths from tuberculosis had therefore decreased by 23,824 and had influenced the aggregate deaths in Prussia, which decreased during that period by 69,064. The year 1886 was a critical year for the general mortality, which during the previous decade—i.e., from 1876 to 1886—had fluctuated between 263·30 and 247·76 per 10,000, whilst it descended to 209 per 10,000 in 1893 and to 180 per 10,000 in 1906. With regard to tuberculosis, the mortality from that disease during the period from 1875 to 1886 was between 31 and 32 per 10,000. From 1887 the mortality due to tuberculosis rapidly descended to 20·5 per 10,000 in 1893 and remained about this level for several years, when it again rapidly descended to 17·26 per 10,000 in 1906. This fact might be attributable either to a reduction in the number of persons attacked or to an increase in the number of recoveries. On an average tuberculous patients died four years after the commencement of the symptoms, so that the decrease of mortality in 1886 would mean that the number of tuberculous patients began to decline in 1882. This was the year when Professor Robert Koch discovered the bacillus of tuberculosis and drew attention to the fact that the disease was spread by the sputum of patients suffering from pulmonary tuberculosis. Moreover, between the years 1882 and 1886 compulsory insurance against sickness became law in Germany and from that time the working classes had at their disposal proper medical advice and financial assistance in the event of illness—a fact which certainly has contributed to the decrease of mortality. It has been alleged that the fall in the death-rate from tuberculosis was only apparent and was in reality due to the circumstance that since the discovery of the tubercle bacillus many suspected cases were now attributed to other diseases. This was, however, erroneous, because the mortality from other diseases of the respiratory organs had not increased in a degree to compensate the decrease of mortality from tuberculosis. It was interesting to find and on the death of George Rainy was selected as Waltonian lecturer on diseases of the eye in the University of Glasgow in 1869. During 30 years he taught and demonstrated the principles and practice of ophthalmic surgery to rising generations, and almost all the ophthalmologists at present in Glasgow have studied with him at some time. The University of Glasgow conferred on him the honorary degree of LL.D. 12 years ago. He retired from public work, both in the University and in the Eye Infirmary, in 1900.

Spitting on Pavements.

The report to the Aberdeen town council by the medical officer and sanitary inspector recommending notices against spitting on the pavements has been adopted. It is suggested that these notices should be not more than 200 yards apart in the busy parts of the streets and should read, "Please do not spit on footpath." It is also suggested that notices should be supplied to the larger factories and workshops in the city and that those notices should bear reference to the main purpose of the discouragement of spitting in public or occupied places—namely, the prevention of the spread of consumption—and that they should read: "Corporation of Aberdeen. Public Health Department. Prevention of Consumption. You are earnestly requested to abstain from the dangerous and objectionable habit of spitting."

May 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish University Bill.

THE names of the members of the first Senate of the new University to have its seat in Dublin are given below; the nomination of those marked with an asterisk has effect only while those persons hold the offices of which the descriptions are attached to the respective names, and on the occasion of any such person ceasing to hold the office a vacancy will occur to be filled by further nomination: *Alexander Anderson, M.A., LL.D. (President of the Constituent College in Galway); the Hon. Mr. Justice Dunbar Plunket Barton; S. H. Butcher, M.P., LL.D.; Sir W. F. Butler, G.C.B.; W. F. T. Butler, M.A.; *D. J. Coffey, M.A., M.B., B.Ch. (President of the Constituent College in Dublin); A. W. Conway, M.A.; M. F. Cox, M.D.; Rev. W. Delany, S.J., LL.D.; A. Dempsey, M.D.; S. Gwynn, M.P.; Sir Stanley Harrington; Miss Mary T. Hayden, M.A.; His Grace the Most Rev. Dr. Healy, D.D.; Douglas Hyde, LL.D.; J. S. McArdle, M.Ch.; J. A. McClelland, M.A., D.Sc.; John MacNeill, B.A.; W. Magennis, M.A.; Thomas Maguire; the Right Rev. Monsignor Mannix, D.D., LL.D.; H. C. McWeeney, M.A.; Rev. A. Murphy; Sir C. Nixon, Bart., M.D., LL.D.; J. F. O'Carroll, M.D.; P. A. O'Sullivan, M.D., B.Ch.; the Right Hon. Christopher Palles, LL.D., Lord Chief Baron; C. Yelverton Pearson, M.D., M.Ch.; J. P. Pye, M.D.; P. Semple, M.A.; A. Senier, Ph.D.; G. Sigerson, M.D.; L. A. Waldron, M.P.; His Grace the Most Rev. Dr. Walsh, D.D.; and *B. C. A. Windle, M.A., M.D., D.Sc., F.R.S. (President of the Constituent College in Cork).

Housing of the Dublin Poor.

The question of the housing of the Dublin poor has been again brought very emphatically under the notice of the assembled Dublin corporation by Dr. J. C. McWalter; and in a leading article the *Freeman's Journal* has spoken out vigorously and wisely regarding some of the curable disorders in the construction of the city.

> It is the rightful boast of Germany that in the cities of the Empire, with only one possible exception, "slum streets" are paved and cleaned and sun-lit just as necessarily as the quarters of the well-to-do. And even the very poorest cannot do their daily shopping at the corner of their meaner street without breathing the pure air of some wide thoroughfare, gladdened by trees and flowers, and pleasant to sit in and lounge and gossip in a while. That sweetens the day, and you see it in the people's faces and habit, and they are cheerful and cleanly and self-respecting; there is content and hope in their friendly faces. Even those who do not live in slums have something to complain of here in Dublin. The slums poison their day, too, and cast up their evil in very visible form. And there is a hideousness of another kind forced upon us at every turn. The advertisement hoardings, with their gaudy persistence, often offending the minds by their unpleasant tales, and the eyes by their crude colours and misdrawn figures, and often by their distressingly weather-battered and ragged state—these, insistent in Dublin beyond the ordinary, take away the dignity of our city, make it look out at elbows and decayed. If we cease sometimes by use to notice their unloveliness, it is that the mischief has gone the more sadly deep. The foreign visitor is disgusted at this ugliness enthroned. In no country is this doubtful trade so unabashedly rampant as here; in the whole of Germany it is hard to find one such offence. The neat advertisement pillar does the business, and the hoarding flamboyance is ruled out by law.

As every human unit is largely influenced by environment, and more especially the younger ones on whom the future of humanity depends, I trust that these suggestions may bear their much-needed fruit.

Injunction Sought against Derry Lady Poor-law Guardian.

Some of the best work in the unions of the Irish metropolis of recent years has been effected by two of the lady Poor-law guardians, Mrs. MacDowel Cosgrave and Mrs. J. Wyse Power, and the value of their efforts has been generally recognised. A lady guardian in the city of Londonderry who has desired to show similar activity has not found public approval, for an action has been brought by the guardians of Derry union against Mrs. Margaret Morris, a lady member of the board, by which the "plaintiffs seek an injunction against defendant to restrain her from entering the workhouse infirmary or from visiting it except in accordance with the rules and regulations for visitors." The evidence led Mr. Justice Barton to state that his "inference from the evidence was that although this lady may have shown a certain want of discretion she did a good deal of good." The defence was that the lady "saw too much," and it would appear to have a solid foundation. One of the things which she saw and exposed to general view was: "The cot incident, three children being in it together, one of whom was seriously ill." Another source of trouble was: "She discovered a child was born in the institution and that the reputed father was an inmate." She also had complained of the quality of the beef-tea and other items. The repeated discoveries and reports of Mrs. Morris roused the conservative antagonism of her colleagues so thoroughly as to lead to the action which is now proceeding.

The Strain of Life in the Irish Constabulary.

What appears to be one of the incidental results of the troubled contemporary history of Irish land tenure has occurred near Dundalk, where a member of the Irish Constabulary who had been in charge of the police hut on an evicted farm was committed on Saturday (May 2nd) to a lunatic asylum. From the beginning of the week it had been noticed that his conduct was growing strange. Two of his comrades accordingly kept watch, and as he was seen putting a loaded revolver in his pocket and retiring to the rear of the hut they followed and he was deprived of the weapon after a desperate struggle. On the following day he attempted to commit suicide with a knife. A medical officer was consulted and the constable was certified to be insane, the strain of the duty which he was engaged in performing having preyed upon his mind in his solitary position to this degree.

The Importance of Union Rate-books.

An interesting communication was made to the Royal Society of Antiquaries at its quarterly meeting on April 28th by Mr. Thomas Laffan of Cashel, the subject of the paper being the importance of the union rate-books of the country, which contain exact records of the valuation, acreage, rent, &c., of every holder of land throughout Ireland. These books are much more copious in their information than the old hearth-money returns which are now so highly prized for purposes of family and historical research and record. In many cases where the parish records failed the rate-books have been found to afford valuable help to those interested in the recovery of property, while from a medical point of view it is a misfortune that many of them have been destroyed and that no copies have been preserved in the general valuation office. Medical statistics are playing an important part in preventive medicine and many medical men will concur with Mr. Laffan in his high estimate of the importance of the union rate-books and in his suggestion that for the future these records should be carefully preserved.

The Belfast Health Commission.

At a meeting of the corporation of Belfast held on May 1st it was decided to refer the report of the Belfast Health Commission to the joint public health, improvement, works, and market committee, with instructions to consider the conclusions arrived at and the recommendations made by the Commission and to report thereon to the council at an early date.

Analysing Creamery Milk.

A case in which great public interest was centred was heard at Magherafelt quarter sessions (county Derry) recently a number of experiments which had been made at his hospital which went to discredit the value of fumigation as a means of preventing the spread of disease. Dr. W. J. Dobbie, superintendent of the free hospital for advanced cases of tuberculosis at Weston, read a paper on Tuberculosis as a Social Problem. He urged the importance of the adoption of educational methods to stir up public opinion and suggested that centres of activity should be established in every city, town, and county. Dr. Gordon, of the Gravenhurst Sanatorium, advocated commencing the education campaign in the public schools. Dr. Helen MacMurchy, Toronto, read a practical paper on the Milk-supply. Dr. Charles Sheard, Toronto, city medical health officer, would keep out visitors to the patients in the hospitals. The following officers were elected: President, Dr. W. J. Dobbie; first vice-president, Dr. A. D. McIntyre, Kingston; and secretary, Dr. J. N. E. Brown, superintendent of the Toronto General Hospital.

Vancouver General Hospital in 1907.

There were 2301 patients admitted for treatment into the wards of the Vancouver, B.C., General Hospital during the year 1907. This was an increase of 988 over 1906. The average duration of stay in the hospital was, however, lower —19·90 days as compared with the previous year of 21·10. There were 135 deaths during the year and of these 47 had been in the hospital less than 48 hours. 11 of the deaths were due to tuberculosis of the lungs. Three "Christian Scientists" were among the cases admitted. During the year the new isolation buildings were put into use, and at times considerable difficulty was experienced in securing accommodation for the cases of infectious diseases admitted. The training school for nurses in connexion with the Vancouver Hospital has been increased from 31 pupil nurses to 53. There were 146 applications for entrance to the school during the year.

Hospital Extension in Winnipeg.

The work of the Winnipeg General Hospital has increased to such an extent during the past few years that new buildings are urgently needed. It has been decided to submit a by-law to the ratepayers of that city to raise $225,000 for hospital extension purposes. Of this amount $100,000 will be for an isolation hospital with 80 beds; morgue, $15,000; hospital for tuberculous patients, $40,000; and maternity and children's hospital, $60,000. The expenditure in maintaining this hospital in 1907 was $169,000. There were received from private patients $23,000 and from semi-private patients $34,000. The average full cost of a private patient per day was $3·00 and for a semi-private patient $1·50. The hospital receives an annual grant from the city of Winnipeg of $40,000 and from the Manitoba Government about $26,000.

(FROM OUR OWN CORRESPONDENT.)

Prize Essay on Bright's Disease.

IN 1901 the New York Academy of Medicine offered a prize for the best original research work on the kidneys. The prize fund was established by a lady and was to be awarded triennially. This is the first time since 1901 that a thesis has been submitted which, in the judgment of the committee, reached the high standard of merit required. The winner of the prize will receive the original amount, plus the interest which has been accumulating since the fund was started, making in all about $20,000. The work involved in this research has been immense in detail. The hospitals employed in the research were Roosevelt, St. Luke, and the Sloane Maternity, while at the same time expert chemists carried on their investigations in the Pathological Laboratory and at the Laboratory of Biological Chemistry of the College of Physicians and Surgeons. The thesis is not published, but the winner of the prize, Dr. Norman Ditman, states that the investigation was along these lines—viz., the identification of the various poisons in the system causing Bright's disease; the probable physical conditions leading to the formation of these poisons; the deduction of a general cause from all of these; and the hypothesis for the probable prevention of the disease.

Visit of Dr. Robert Koch.

The visit of Dr. Robert Koch of Germany to this country has excited a widespread interest in medical and scientific circles. His first public appearance was at a dinner given by the German Medical Society, under the presidency of Dr. Carl Beck. An interesting incident of the dinner was a telegram from the German Ambassador at Washington, expressing the Emperor's great appreciation of Mr. Carnegie's generous gift of $100,000 to the "Robert Koch *Stiftung*," which he was sure would further the international fight against tuberculosis. Dr. Koch expressed his appreciation of the cordial reception given to him in simple but forceful language, asserting that he had endeavoured, like many others, to do his work in the world as opportunity offered. He esteemed himself fortunate in having found gold in the dust of the road which is open to everyone. He closed with a promise that he would return, which was received with great enthusiasm.

Conference on Medical Education.

The fourth annual conference on medical education was recently held in Chicago. In his address the President, Dr. Bevan, announced the merging of several medical schools as an important event, showing a tendency to close weak schools and in their places to create one strong and well-endowed college. It appeared in a report that 50 leading medical colleges will in 1910 be requiring one or more years' study in a college of liberal arts, including courses in physics, chemistry, and biology. President Eliot, of Harvard University, spoke at length regarding high standards of preliminary education and called attention to the fact that the colleges holding high standards are more likely to secure endowments. The conference was addressed by Dr. A. H. F. Barbour, of the University of Edinburgh, who explained the medical standards in Scotland. The outlook for great advances towards a higher grade of qualification on admission to the medical colleges, longer terms of study, and more efficiency in teaching was never so promising.

Interstate Health Investigations.

The importance of coöperation of the Federal Government with State and local health authorities in the control of widespread epidemics has been repeatedly demonstrated during the last few years. But the "State rights" doctrine has been so tenaciously adhered to that the "public health service," which represents the General Government, has been able to bring to the aid of local health authorities a very limited amount of its resources. A Bill is now before Congress which greatly enlarges the scope of the powers of the "public health service" in the aid of the State and local sanitary boards. The Bill provides that the Federal service may make special investigations in all parts of the country into the prevalence of diseases, the conditions affecting their origin and spread, and the means of prevention; while the surgeon-general may detail officers to aid localities and may establish hygienic laboratories and take other necessary means to control epidemics. If this measure becomes a law it will create a national system of sanitary police of great efficiency.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Proprietary Medicines.

Messrs. E. Glover and J. A. Kenningham have arrived in Melbourne as delegates from a number of proprietary firms having an interest in the manufacture of patent medicines, to protest against the legislation introduced, and contemplated, by the Federal Government. On March 10th they were introduced to the Minister of Customs. Mr. Glover stated that he represented about 300 proprietors of patent articles, including soaps, medicines, &c. These business people had held a trade connexion in Australia for many years and wished to continue it, but if the Government demanded that formulæ should be disclosed they would have to give up the Australian market altogether. Mr. Kenningham said that they were informed that if a formula was disclosed it was open to anyone to make the goods and to call them by the correct names. The Minister, in reply, said that they could depend that the Government would try to treat them with reason and justice. Any legislation that was passed would, he hoped, be of a reasonable character. Black sheep had been referred to as being in the trade in proprietary articles. The more that trade was probed that the decrease was greater in the towns and Professor Fraenkel was inclined to attribute this to the circumstance that in the towns a larger proportion of the population profited by the operation of the workmen's insurance laws than in the rural districts. The same cause was alleged for the greater decrease of mortality in the industrial western districts of Prussia than in the agricultural eastern districts. The decrease of mortality from tuberculosis was especially marked at the more advanced ages. Comparing the years 1886 and 1906 the reductions per 10,000 at successive age-periods were as follows: under 15 years, 4·70; from 15 to 30 years, 8·61; from 30 to 60 years, 24·77; and over 60 years, 45·46. For some other German States—namely, for Bavaria, Saxony, Würtemberg, and Baden—the statistical returns were given only for the period between 1892 and 1902, the decrease of the death-rate from tuberculosis in these countries being 3, 4, 1, and 4 per 10,000 respectively. Professor Fraenkel then compared the Prussian statistical returns with those of Great Britain and Ireland. He said that in England the death-rate from tuberculosis decreased between 1864 and 1904 from 33 to 18 per 10,000, and in Scotland from 36 to 21 per 10,000, so that in those countries the decrease during 40 years was the same as in Prussia during 20 years. Alluding to the mortality from tuberculosis in Ireland (which had increased from 24 to 27 per 10,000 within the period from 1864 to 1905), he said that this increase was caused by the unsatisfactory standard of living which prevailed among the population. It proved, however, that the bacillus of tuberculosis had not become less infectious or the resistance of the human species greater, as had been asserted by some writers desirous of making out that the diminished mortality from tuberculosis was due to natural causes. If their arguments were sound the mortality of tuberculosis would have become smaller in Ireland also; its increase implied that the mortality from tuberculosis was influenced not by natural causes but by purposely directed measures such as amelioration of the social condition of the population, general hygienic improvements, and the systematic observance of the special precautions which have been recommended for the prevention of tuberculosis. Tuberculous patients being the vehicles of infection all those measures were especially efficacious which tended to the recovery or at least the isolation of the individual patient. This was the principal function of the sanatoriums, and it was remarkable that the mortality from tuberculosis, which remained nearly the same from the year 1899 to 1905, decreased by 2 per 10,000 in 1906, coincidently with the development of the sanatorium movement. About 40,000 persons were admitted every year into the sanatoriums and of these about 20,000 had obvious tubercle bacilli in their sputum. In about 6000 of them the tubercle bacilli disappeared from the sputum under the sanatorium treatment and in this way these patients became incapable of spreading the disease. Professor Fraenkel was therefore a firm believer in the value of sanatoriums for the prophylaxis of tuberculosis. In the discussion Dr. Mosse mentioned that Dr. Croissant of Heidelberg had compared the results obtained within and outside the sanatoriums respectively. He found that of the patients in the first stage of the disease 79·6 per cent. became able to work when treated and 82·5 per cent. when not treated in a sanatorium. Dr. Mosse also drew attention to the fact that the mortality from tuberculosis in England had decreased although the number of sanatoriums was rather small compared with Germany. Measures to improve the standard of living among the population were more efficacious than sanatoriums. Dr. Albert Fraenkel said that the sanatoriums, as a rule, received only patients in the first stage, or suspected cases, who might recover without sanatorium treatment. It was, however, very necessary to establish sanatoriums for patients in an advanced stage who were especially dangerous as disseminators of the bacilli. Dr. Hamburger quoted from the statistical returns of Paris, where the mortality from tuberculosis decreased from 45·1 to 35·8 per 10,000 during the period from 1865 to 1905. It was remarkable that a slight increase was observed in the period from 1881 to 1890—namely, at the very time when the tubercle bacillus was discovered. Several other members took part in the discussion; the general opinion, with a few exceptions, was that sanatoriums in their present state, although, of course, valuable for individual patients, were not so important for the general prevention of tuberculosis as Professor Fraenkel supposed.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Regulating the Sale of Patent Medicines.

Senator Templeman of British Columbia has a Bill before the Canadian Parliament dealing with patent medicines which will inform the public of the character of the drugs used in these preparations in Canada. It only has to do with those drugs or preparations which are not found in the British Pharmacopœia, the Codex Medicamentarius of France, the Pharmacopœia of the United States, or any other pharmacopœia approved of by the Minister in charge of this branch of the public service. The pivotal clause of the Bill is that which treats of the contents of medicines. This clause sets forth the names of the drugs which shall not enter into the composition of preparations to be manufactured, imported, or exposed for sale. The purport of the Bill is to rule out cocaine and alcohol in drug preparations; and if these drugs are used it must be so stated on the labels. The Bill further provides for governmental inspection in carrying out the law.

Meeting of Ex-House Surgeons of Toronto General Hospital.

The third annual dinner and meeting of the Association of Ex-House Surgeons of the Toronto General Hospital took place in Toronto on April 15th, being presided over by Dr. Alexander Taylor of Goderich. There were 40 ex-house surgeons present, including Dr. T. B. Futcher, associate professor of medicine in Johns Hopkins University, Baltimore, U.S.A. Dr. Charles O'Reilly, former superintendent of the hospital, and Mr. P. C. Larkin, vice-chairman of the board of trustees, replied to the toast "Our Guests." In the course of his remarks Mr. Larkin announced that he would give a valuable prize to the ex-house officer who made the best contribution to medical literature between now and the time of the next annual meeting. The annual election of officers of the association resulted as follows: President, Dr. Taylor, Goderich, Ontario; vice-president, Dr. Fred. Fenton, Toronto; secretary, Dr. J. N. E. Brown, superintendent of the Toronto General Hospital; treasurer, Dr. W. B. Hendry, Toronto; general council, Dr. W. J. Charlton, Weston, Ontario; Dr. H. A. Bruce; and Dr. E. Stanley Ryerson, Toronto.

A New University for Western Canada.

The new University of Alberta is to open in September with a class of 40 students. The first meeting of the senate was held recently. Three medical men are members thereof—namely, Dr. W. D. Ferris, Dr. W. S. Galbraith, and Dr. O. Boyd. The President is Professor H. M. Tory, LL.D., brought by the Government of the province of Alberta from McGill University, Montreal. To him has been assigned the preliminary work of organisation. The site of the new University is at Edmonton and the extent of the ground is 258 acres. The current expenses are to be defrayed by a grant of 20 per cent. of the corporation tax and 20 per cent. of the unoccupied land tax. The Government will provide the buildings. Professor Tory has stated that courses will be instituted leading to the degrees of B.A. and B.Sc. The college yearly session will be divided into two terms beginning at the end of September and the beginning of February. Each term will be complete in itself and will be followed by an examination.

Anti-tuberculosis Society in Newfoundland.

A large public meeting has been recently held at St. John's, Newfoundland, and a society established to prevent the spread of tuberculosis in that colony. His Excellency the Governor of the island, himself a medical man, presided at the meeting. The Hon. John Harvey was appointed to the position of president of the new society and Dr. Rendell and Mayor Gibbs, vice-presidents, with a number of prominent citizens, medical and lay, as an executive committee. As tuberculosis has been increasing to an alarming extent in the colony the formation of the association is opportune.

Canadian Hospital Association.

The Canadian Hospital Association met in Toronto in annual convention on April 20th and 21st, under the presidency of Miss L. C. Brent, superintendent of the Sick Children's Hospital, Toronto. In her annual address she recommended that the membership of the association should be extended to include trustees of hospitals and other laymen interested in hospital work. Dr. A. D. McIntyre, superintendent of the Kingston General Hospital, in a paper quoted well liked by his fellows. He obtained the L.S.A. in 1882 and the M.R.C.S. Eng. and L.R.C.P. Lond. in 1883. After leaving St. Thomas's he was appointed house physician at the City of London Hospital for Diseases of the Chest. Soon after qualifying, when 25 years of age, he obtained the post of medical officer to the North Surrey District Schools at Anerley in competition with 70 other applicants and then settled at Anerley. In the course of a few years he had succeeded in acquiring a large practice which grew from year to year and became one of the most extensive in South London. In the year 1901 he was appointed medical officer of health to the Penge urban district council and when the London County Council built its residential school at Anerley for the deaf and dumb he was appointed medical officer to that school. He was keenly interested in his profession and was for many years honorary secretary first of the East Surrey, and latterly of the Norwood, division of the British Medical Association. In addition he was a member of the Sydenham District Medical Society and of the Beckenham and Penge Medical Society, and in him the various charities in connexion with the profession found a generous supporter. He was at all times a keen sportsman and a lover of outdoor sports. When at St. Thomas's Hospital he played half-back in the Rugby XV. and was a member of the team which won the Inter-Hospital Cup in 1878, the first occasion on which the cup was won by St. Thomas's. He subsequently took up lawn-tennis, played for the Crystal Palace Club for many years, and won many prizes. Finding that his health and the claims of practice would not permit him to keep up tennis he turned to golf and was a member of the Beckenham Golf Club where he won two challenge cups. He was very good at all sports and his success was all the more remarkable because he had so little time to devote to them and could never practise regularly. It was his interest in sport that led to his accepting the post of honorary medical officer to the Crystal Palace Football Club and practically the last work that he did was when he attended a prominent member of the eleven who was injured in a match on Saturday, April 18th. He conveyed the patient to his home in Croydon in his motor-car and in doing so caught a severe chill. He was taken ill on that Saturday night and died on the morning of Friday, April 24th. As a result of a post-mortem examination the coronary arteries were found to be atheromatous.

Henry Prangley was a keen and enthusiastic Freemason of many years' standing. He was a Past Master of the Anerley Lodge, No. 1397, and M.E Z. of the Anerley Chapter. He was a founder of the Cheselden Lodge, No. 2870 (St. Thomas's Hospital), of which he was at the time of his death Worshipful Master. He was also a founder and P.Z. of the Cheselden Chapter. Devoted both to his old hospital and to Freemasonry, it afforded him great gratification to be called upon to fill the principal offices in the Cheselden Lodge and the Cheselden Chapter, and although in the case of the Lodge it was not given to him to complete his work the brethren will feel a melancholy satisfaction in that for a time they were privileged to serve under his rule. His sudden death will be most sincerely lamented by the brethren of the Masonic bodies with which he was associated. Indeed, not only amongst Freemasons but, speaking generally, his death will be a blow peculiarly and severely felt by his friends, by his patients, and by all who knew him. As a general practitioner he reflected credit upon the great body of the profession. As a man he was able, upright, genial, and considerate, and popular in the best sense of the term—a good man and true. The funeral service took place on April 29th at St. Paul's Church, Upper Norwood (the body having been previously cremated at Golder's Green according to the wishes of the deceased), and the ashes were subsequently interred at the Crystal Palace District Cemetery, Elmers End. There was a very large number of mourners present and the whole of the route was lined by people. Besides the wreaths on the coffin it took three carriages to convey the other flowers, which included wreaths sent by the Anerley Lodge and the Anerley Chapter and the Cheselden Lodge and the Cheselden Chapter. In addition to the principal mourners the Anerley Lodge was represented by Mr. P. W. Greetham, W.M., Dr. R. Wilkinson, I.P.M., and other members of the Lodge, whilst the Cheselden Lodge was represented by Mr. L. A. Bidwell, I.P.M., Dr. Crawford Thomson, Dr. W. S. Colman, Dr. O. R. Box (all Past Masters of the Lodge), Rev. Herbert Sheppard (chaplain), and several other members of the Lodge. The funeral was also attended by members and officials of the Penge urban district council, of the North Surrey District Schools, and representatives of the Deaf and Dumb School, and the postmen who were accompanied by their band. The service at the church and at the grave was conducted by Canon Ransford. Mr. Prangley leaves a widow to whom we tender our sincere sympathy.

WILLIAM BOWEN DAVIES, L.R.C.P. LOND., M.R.C.S. ENG., L.S.A.

BY the death of Mr. William Bowen Davies at the age of 61 years the town of Llandrindod Wells has lost a friend and benefactor of a very unusual order, a man who devoted his life to the advancement of its welfare and served it in many offices of great utility. Mr. Davies was the eldest son of the late Mr. Thomas Davies of Llandingat, Carmarthenshire; he was educated at Llandovery College and later at St. Bartholomew's Hospital, whence he qualified at the London Colleges and the Apothecaries' Hall in the years 1869–70. He then held a resident post for a year in the Jersey General Infirmary and in 1872 proceeded to start in practice at Llandrindod Wells, then little more than a village, where the death of his only professional competitor speedily placed him in the enjoyment of an extensive practice, which he held until his retirement, in the surrounding district. Public medical appointments were soon added to his private work, for he became public vaccinator and medical officer of health of the Rhayader union, and in 1881 the first medical officer and secretary of the Llandrindod Wells Cottage Hospital and Convalescent Home, an institution which he was a prime agent in establishing. In 1903 he retired to the consulting staff of the hospital. Soon after his settlement in the town he became acquainted with its mineral waters and consequently impressed with its potentialities as a Spa for the treatment of disease; accordingly he set himself to the study of balneology and hydrotherapy to such purpose that he was able to impress the advantages of Llandrindod Wells in this connexion upon his own profession to the very great benefit of the place. His enthusiasm for the subject was reflected in many writings and subsequently gained him the presidency of the British Balneological and Climatological Society. He also took an interest in the promotion of the Spa by journalism and was a chief promoter of the first local newspaper. In 1884 he held the presidency of the Shropshire and Mid-Wales branch of the British Medical Association and delivered his address from the chair on Llandrindod Wells as a Health Resort. He gave very valuable advice to his town upon the subjects of sewerage, water-supply, road improvement, and lighting, and lived to see the electric installation which he had long advocated. Under his management a sample of saline water was sent from the Spa to an exhibition at Frankfort where it was awarded a bronze medal, a distinction which gave Mr. Davies the greatest pleasure. The result of all this work was that Llandrindod Wells became a justly popular health resort, a consummation which it owes largely to the subject of this memoir. His other public activities were concerned chiefly with three interests, the welfare of the Anglican church in his town, of which he was churchwarden for many years of whole-hearted service, the struggle to obtain proper local government for its local affairs, and the education problem for his district. He was one of the first aldermen to be appointed to the Radnorshire county council on its formation in 1889, a body which since 1891 has met at Llandrindod Wells. This opportune change of venue gave the town sufficient distinction to be granted a local board of its own, of which Mr. Davies was unanimously elected chairman, holding office until in 1894 this body was succeeded by an urban district council, the chair of which he was again chosen to fill, for his advice on sanitary matters was found to be of the utmost value to the town. He devoted untiring attention to this office, although at the same time he was carrying on a large professional practice, was a commissioner for taxes, and had also been placed on the commission of the peace. He was equally untiring in his efforts to spread the knowledge of the Spa's merits and among the contributions to literature which he made with this object were "A Report on the Medicinal Properties of the Mineral Waters at Llandrindod Wells," "A History of Llandrindod Wells," and "The Spa Treatment of Arthritis Deformans." He took a keen and practical interest in meteorology and compiled systematic records of local weather conditions and rainfall. He was a promoter of the eisteddfods held at Llandrindod Wells, and in fact joined enthusiastically in every enterprise into the more black sheep were discovered. The Government had got past the stage of relying on sworn statements to prevent people being deluded or practically poisoned and intended to leave such matters to an analyst who would be appointed for the Commonwealth. The Bill alluded to only intended to stop injurious importations and impostures. He was glad to hear the delegates say that the statement about the withdrawal of advertisements was not a threat. He would carefully consider what the delegates had placed before him. Certain powers were proposed to be given that would permit the Governor-General in Council to prescribe in certain cases that formulæ need not be disclosed. Since then the delegates have made further representations of a similar nature and have attached the following letter to their memorandum; the signatures are those of all the leading wholesale druggists and other influential mercantile firms:—

> We, the undersigned, wholesale distributors of patent and proprietary medicines and foods, beg to state that we have heard the views expressed by the delegates from the Proprietary Articles Section of the London Chamber of Commerce, and agree with them that it would be impracticable to demand that proprietors should reveal their formulæ, as such disclosure would result in the total loss of their trade rights. We believe that the alternative proposal they put forward will effectually safeguard the public, and, at the same time, eliminate from the market undesirable articles, viz., that a list of deleterious and objectionable drugs and poisons be scheduled, and that all proprietors be called upon to make a declaration whether their goods do or do not contain any of these ingredients.

Loss on Condemned Carcasses.

Mr. Brown, the Victorian supervisor of export food-supplies, has been giving close consideration to the question of compensating butchers for losses by the condemnation of purchased beasts. He has come to the conclusion that the butcher is the last man on whom the loss should fall, as he buys the animals in yards where they are passed by inspectors as sound. No man living can tell how a live beast showing no sign of disease will turn out when slaughtered. Dr. Brown suggests that the agents should increase their selling charge ¼ per cent. and that a fund should be established to cover the losses if condemned. As an alternative Dr. Brown would favour any workable scheme by which the loss would fall on the particular owner whose beasts are condemned, though the apparent objection to the first proposal is minimised by the fact that nearly every grazier becomes possessed of diseased stock sooner or later, so that he would not as a rule contribute to a fund merely for the benefit of others. Dr. Brown is convinced that some remedy is called for.

"Nature Study" and Enteric Fever.

The Education Department of Victoria has recently made a great feature of "nature study" for State school children. At Beechworth, a country centre, enteric fever has been very prevalent of late, and the local health officer, Dr. D. Skinner, in a report on ten cases coming under his notice, remarked: "In several of the cases I have found that the sufferers had been hunting for tadpoles in the dirty pools of Spring Neck and Holme's Neck, which are nothing but collections of sewage of the filthiest type. This is part of the 'nature study' which is at present one of the fads of the Education Department. But I should say that a little study of the local sanitary conditions would be of much greater advantage to both the rising generation and their teachers." The council directed that copies of the report should be forwarded to the Board of Public Health and to the head master of the school.

Personal Items.

Dr. Henry Maudsley of Melbourne is leaving by the *Asturias* for a short visit to England. Dr. Maudsley was entertained at dinner by a number of fellow members of the profession who wished him a pleasant trip.—Sir Thomas Fitzgerald has recently suffered from a severe attack of pneumonia and at one period of his illness his condition gave rise to grave concern. He has now convalesced satisfactorily and has been able to go to Sydney for a change.—The David Syme Research Scholarship in the University of Melbourne has this year been awarded to Dr. Basil Kilvington for his work in the healing and degeneration of nerves. The award carries a monetary value of £100.

April 6th.

Obituary.

CHARLES EDWARD UNDERHILL, B.A., M.B. Cantab., F.R.C.S. Edin., M.R.C.S. Eng., F.R.S. Edin.,

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

For the first time in its history the Royal College of Physicians of Edinburgh has had to mourn the death of the occupant of its presidential chair. The occurrence has been felt deeply owing to the very special position which the President occupied. Few men in Edinburgh have called out such steady esteem and admiration, deepening into affection, as did Dr. C. E. Underhill. The knowledge that when last year he accepted the presidential chair he was suffering from aortic disease added a note of heroism to his occupancy of it and elicited the generous admiration which quiet and steadfast pluck tends to do. Those who knew him intimately had the greatest admiration for the kindly courtesy of his manner, the straightforwardness of his life, the purity of his motives, the soundness of his judgment, and the culture of his mind. He was a loyal friend and of enemies he can hardly be said to have had any. Such a man is a very valuable possession in a medical community and it is well that his brethren and his College should so truly mourn his loss. It was first and foremost as a man that Dr. Underhill made his impress upon the profession. He did not write much, but what he did write would have vindicated a claim to write more had he been so minded. He life was devoted to his patients inside the hospitals and to a large and influential *clientèle* in Edinburgh and its neighbourhood. He died on April 24th and was buried on the 28th in the Dean Cemetery. The service was held in the church of St. John the Evangelist, Bishop Dowden taking part in it. The Fellows of both Colleges attended the funeral in their official robes.

Charles Edward Underhill was born in 1845 and was the second son of Mr. Lees Underhill, F.R.C.S., of Tipton, Staffordshire. He was a graduate of Cambridge, having taken his B.A. degree in 1867 and his M.B. degree in 1870. He completed his medical studies in Edinburgh and became assistant to Dr. Matthews Duncan. When Dr. Duncan went to London Dr. Underhill succeeded to much of his practice. He became a Fellow of the Royal College of Surgeons of Edinburgh in 1872 and of the Royal College of Physicians four years later. He was one of the physicians to the Maternity Hospital for many years and served as a physician to the Royal Hospital for Sick Children. He held the double office of medical officer of health and police surgeon to the city of Edinburgh. He was for many years treasurer of the Edinburgh branch of the British Medical Association. He became president of the branch more recently. He was a past president of the Edinburgh Royal Medical Society, of the Edinburgh Obstetrical Society, of the Edinburgh Medico-Chirurgical Society, and of the Edinburgh Harveian Society, and he was thus a prominent member of the most distinguished medical circle in Edinburgh. In every position which he held he gained but one opinion as to the admirable manner in which he discharged the duties.

Dr. Underhill had no family and is survived by Mrs. Underhill, with whom much sympathy is felt. The funeral was attended by four brothers and one cousin, all members of the medical profession.

HENRY JOHN PRANGLEY, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A.

We sincerely regret to announce the death, after a few days' illness, from angina pectoris of Mr. Henry John Prangley, well known and highly esteemed as a practitioner in Anerley and the neighbourhood, at the comparatively early age of 50 years. He was the son of Mr. John Pearce Prangley, solicitor, of Heytesbury, in Wiltshire, and was born in that town on Sept. 14th, 1857. His school days were spent at St. Nicholas College, Hurstpierpoint, where he took many prizes, showing a particular aptitude for mathematics. On leaving school he was apprenticed to Dr. Willis, who was medical officer of health of Monmouth, and subsequently proceeded to St. Thomas's Hospital which he joined in 1875. Whilst at the hospital he both worked and played with the energy which characterised him and as a student, as indeed throughout his life, he was drive to Ospedaletti, a sheltered bay between Bordighera and San Remo. A trip by steamer was arranged to Monte Carlo for the 16th. The whole of the proceedings passed off with great *éclat*.

Sir Samuel Wilks who underwent a somewhat serious operation upon May 1st is, we are glad to be able to state, progressing favourably.

FREEMASONRY.—Dr. Samuel West, F.R.C.P., and Dr. Charles Wells have had the honour of being appointed Grand Officers of the United Grand Lodge of England.

PRESENTATION TO A MEDICAL PRACTITIONER.—At the distribution of certificates to the Dartmouth corporation fire brigade class of the St. John Ambulance Association on April 25th Mr. John Henry Harris, M.D. Durh., M.R.C.S. Eng., L.S.A., was presented with a silver cigarette case as a mark of appreciation of his services as honorary instructor.

THE ROYAL SANITARY INSTITUTE.—A discussion will be held in the Music Hall, Shrewsbury, on Saturday, May 23rd, at 11 A.M., on "The Inspection of Dairies and Cowsheds," which will be opened by Mr. T. W. H. Garstang, D.P.H., medical officer of health, Bucklow R.D.C., under the chairmanship of Colonel J. Lane Notter, R.A.M.C., deputy chairman of the council of the Institute. General discussion is invited. In the afternoon a visit will be made to the Shrewsbury Sewage Farm.

DONATIONS AND BEQUESTS.—The late Mr. C. E. Gael, of Charlton Kings, Gloucestershire, has bequeathed £500 each to the Cheltenham General Hospital, the Delancey Fever Hospital, and the Cheltenham Eye, Throat, and Ear Hospital.—£2300 have been received already towards the fund for reducing the debt of the Royal Devon and Exeter Hospital. This includes £1000 from the late Mr. R. Wood of Sidmouth, £1000 from Mrs. Nosworthy of Dawlish, and £20 from Viscount Sidmouth.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.—In response to the desires of a number of school medical officers arrangements are being made for a short course of lectures and demonstrations to be given in London during Whit-week. Dr. James Kerr, Dr. H. Meredith Richards, Dr. C. J. Thomas, and other experienced medical inspectors have already promised to give addresses, and demonstrations of the details of actual medical inspection will also be arranged. School medical officers desiring to avail themselves of the course are requested to communicate with Mr. W. A. Lawton, at the offices of the Incorporated Society of Medical Officers of Health, 1, Upper Montague-street, Russell-square, London, W.C.

THE HERTFORD GENERAL INFIRMARY AND DR. J. T. TASKER-EVANS.—On April 30th a testimonial, which had been subscribed for by the governors and supporters of the Hertford General Infirmary, was presented to Dr. J. T. Tasker-Evans upon his retirement from the post of honorary medical officer after 29 years' service. The presentation took the shape of a silver tea and coffee service and silver electro-plated tray, with a cheque for 40 guineas, whilst a gold necklet was presented to Mrs. Tasker-Evans. It is worthy of note that during the course of the proceedings reference was made to a proposal to substitute for the name "Infirmary" the word "Hospital." Unfortunately, in the lay mind the name "*Infirmary*" is associated with Poor-law charity and it would no doubt be of great advantage to the institution in question if the name were changed as suggested.

LONGEVITY.—The Rev. Thomas Lord, Congregational minister of Horncastle, Lincolnshire, has recently celebrated the hundredth anniversary of his birthday, having been born at Olney, Buckinghamshire, on April 22nd, 1808. Mr. Lord is said to take a two-mile walk every day. For 75 years he has been connected with the temperance movement and about a month ago he preached the Band of Hope anniversary sermons at Wainfleet. He has been married three times but is now a widower and resides with his daughter and son-in-law, Mr. and Mrs. C. M. Hodgett. He has been a lifelong non-smoker.—Lord Gwydyr has recently completed his ninety-eighth year, having been born in 1810. He is High Steward of Ipswich, in the neighbourhood of which he resides, and was for many years chairman of the Suffolk quarter sessions. From 1833 to 1870 he was secretary to the Lord Great Chamberlain. He has one son who is himself a grandfather.

ROYAL MICROSCOPICAL SOCIETY.—At a meeting of the Royal Microscopical Society held on April 15th a communication by Mr. J. Strachan on Dendritic Growths of Copper Oxide in Paper was read by Mr. Shillington Scales. Minute particles of copper were found in all kinds of paper, whether composed of linen, esparto grass, or wood pulp, and had no doubt been abraded from the paper-making machinery. The dendritic formation was due to partial solution of those particles and subsequent deposition of insoluble oxide. Mr. F. Enock delivered a lecture on Nature's Protection of Insect Life, illustrated by lantern slides taken by three-colour photography.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next general or quarterly meeting will be held at 11, Chandos-street, Cavendish-square, London, W., on Tuesday, May 19th, under the presidency of Dr. P. W. Macdonald, at 3 P.M. A paper and lantern demonstration on Some Points in the Histology of Lymphogenous and Hæmatogenous Toxic Lesions of the Spinal Cord will be given by Dr. David Orr and Dr. R. G. Rows. A discussion will be introduced by Dr. D. G. Thomson on the Teaching of Psychiatry. Members will afterwards dine together at the Café Monico, Piccadilly-circus, W., at 7 o'clock, when it is hoped that as many as possible will join. The price of the dinner, exclusive of wine, will be 7*s.* 6*d.* Evening dress optional.

THE CHEMISTS' EXHIBITION.—Once again this exhibition is being held in its old quarters at the Royal Horticultural Hall, Vincent-square, Westminster. The stalls are as attractively arranged as usual, and although perhaps there is no special novelty of a striking character shown yet on all sides are found exhibits that appeal not only to members of the drug and allied trades but also fulfil the useful function of bringing before the notice of members of the medical profession the many modifications in the methods of putting up some of the older drugs, whilst at the same time the exhibits illustrate by practical example many of the newer forms of medicaments. The feature that impresses itself most on a visitor is perhaps the great advance that has been made during recent years in the methods of administration of nauseous drugs which have now been converted by the skill of the mixer and compounder into almost attractive sweetmeats. The exhibition opened on Monday and will close to-day (Friday).

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Education of Afflicted Children in Ireland.

MR. CHARLES CRAIG has introduced a Bill into the House of Commons "to provide for the better education of afflicted children in Ireland."

Medical Inspection of School Children in Scotland.

The Scotch Education Bill, which has received a second reading in the House of Commons, contains a clause that school boards in Scotland "may and where required by the department shall provide" for the medical examination and supervision of the pupils attending schools within their districts on lines laid down by the Scotch Education Department. For the purposes of this inspection the boards are authorised to appoint such medical officers as may be necessary. Several speakers in the course of the debate expressed satisfaction that the Government had dealt with this subject in the Bill.

HOUSE OF LORDS.

WEDNESDAY, MAY 6TH.

Official Directory of Nurses Bill.

Lord BALFOUR of BURLEIGH moved the second reading of the Official Directory of Nurses Bill. He explained that after a nurse had left a hospital and set up in practice there was often great difficulty in ascertaining what were her qualifications. His Bill therefore provided that there should be an official directory in which should be inserted the names of nurses with such particulars as the Privy Council might direct. The Bill set forth that "every nurse who has received training in nursing at a hospital, infirmary, or other institution for the cure of the sick in Great Britain or Ireland, and not being an institution carried on for private gain, shall be entitled, on application to the Registrar, to have his or her name entered in the Directory, together with such particulars as shall for the advancement of the town. For many years he was a manager of the national school and took an ardent part in obtaining a county school for his neighbourhood. Unhappily, his health failed during last year and in July he retired to Exmouth in Devonshire where his death took place; there can be no doubt it was accelerated by his extraordinary activity. He was held in the tenderest regard by an exceptionally wide circle of friends, and his funeral, on April 29th, was made a public ceremony, officially attended by his urban district council. Mr. Davies married in 1879 Miss *Jessie* Rankin, daughter of the late Mr. William Rankin of Handsworth, Staffordshire, who, with two sons and four daughters, survives him.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Béchamp, formerly professor of chemistry in the Medical Faculty of the University of Montpellier and corresponding member of the Paris Academy of Medicine. — Dr. Féron-Vrau, formerly professor in the Medical Faculty of the University of Lille.—Dr. Rieshetillo, formerly *privat-docent* of dermatology in the University of Moscow.—Dr. Nabias, professor of materia medica in the University of Bordeaux.—Dr. Gestin, formerly Director-General of the French Naval Medical Service.—Dr. Franz von Leydig who had been professor of comparative anatomy and zoology and director of the Zoological Museum in Bonn for some 12 years until his retirement more than 20 years ago. He was born at Rothenburg, to which town he returned after his retirement and where he remained until his death. Before his appointment to Bonn he was for several years professor in Tübingen. He published a work entitled "Histology, Human and Comparative," in 1857, and later a "Manual of Comparative Anatomy," which, however, never seems to have been completed. His age was 86 years.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following degree was conferred on May 1st:—

B.C.—C. B. Ticehurst, St. John's College.

The special board for medicine has issued new schedules in chemistry and physics which will come into operation at the examination at Christmas, 1908.

FOREIGN UNIVERSITY INTELLIGENCE.—*Breslau:* Dr. Jean Schaffer, *privat-docent* of Dermatology, has been granted the title of Professor.—*Copenhagen:* Dr. O. U. Maalöe has been recognised as *privat-docent* of Pathological Anatomy. Dr. V. Schaldemose has been promoted to an Extraordinary Professorship of Surgery.—*Kieff:* Dr. Laudenbach has been appointed to the chair of Physiology.—*Naples:* Dr. Eugenio Scarpitti has been recognised as *privat-docent* of Medical Pathology.—*St. Petersburg (Military Medical Academy):* Dr. W. Oppel has been promoted to an Extraordinary Professorship of Surgical Pathology and Therapeutics.—*Utrecht:* Dr. H. P. Wijsmann of Leyden has been appointed Extraordinary Professor of Pharmacology and Alimentary Hygiene.—*Vienna:* Dr. Franz Hamburger has been appointed to succeed Professor Frühwald in the charge of the Children's Department of the Policlinic.

LITERARY INTELLIGENCE.—Messrs. Henry Frowde and Hodder and Stoughton will publish during May the second edition of "Operations of General Practice" by Mr. Edred M. Corner and Dr. H. I. Pinches; also the following new books: "A System of Syphilis," Vol. I., edited by Mr. D'Arcy Power and Mr. J. Keogh Murphy; "The Writings of the late Sir William Broadbent, F.R.S.," collected and edited by Dr. Walter Broadbent; "Glandular Enlargements and Other Diseases of the Lymphatic System," by Mr. Arthur Edmunds of the Great Northern Central Hospital; "The Law in General Medical Practice, or Clinical Jurisprudence," by Dr. Stanley B. Atkinson, secretary of the Medico-Legal Society; "Diseases of the Eye," by Mr. M. Stephen Mayou of the Central London Ophthalmic Hospital; and "Gunshot Wounds," by Major C. G. Spencer, R.A.M.C. The above publishers also have in active preparation "Heart Diseases," by Dr. James Mackenzie, author of "The Study of the Pulse," and "The Rectum, its Diseases and Developmental Defects," by Sir Charles Ball.—Messrs. Smith, Elder and Co. have almost ready for publication a work on "Animal Life" by Dr. F. W. Gamble, lecturer in zoology, Owens College, Manchester. The volume comprises a series of studies in the life-history of typical members of the animal kingdom, describing their vital activities in relation to their structure, and the general scheme of development, based upon a series of lectures delivered to the students of the Owens College, Manchester. It will include a coloured frontispiece and numerous line and half-tone illustrations.

UNIVERSITY OF OXFORD.—The following dates of examinations have been announced:—Examination for the Degree of Bachelor of Medicine: Thursday, June 18th, to Friday, June 26th; names to be sent in by 10.30 A.M. on Tuesday, June 2nd. Examination for the Degree of Master in Surgery: Thursday, June 25th *et seq.*; names to be sent in by 10.30 A.M. on Friday, June 5th. Examination in Preventive Medicine: Tuesday, Nov. 17th (Part I.), Wednesday, Nov. 18th, to Friday, Nov. 20th (Part II.); names to be sent in by 10.30 A.M. on Tuesday, Oct. 27th. Natural Science Scholarships: Scholarships in natural science are announced at Balliol and Brasenose Colleges; the examination will commence on Tuesday, June 30th.

ROYAL COLLEGE OF SURGEONS IN IRELAND: GENERAL MEETING AND ELECTION OF OFFICERS.—A meeting of the College will be held on Saturday, May 30th, at 1 o'clock, to receive the annual report of the Council. Notices of motion received by the registrar on or before Tuesday, May 19th, will have priority of consideration over any others which may be submitted. A meeting of the College will also be held on Monday, June 1st, at 1 o'clock, pursuant to the provisions of the Charters, to elect a President, Vice-President, council, and secretary of the College for the ensuing year. Fellows who may desire to have their names printed on the list of candidates for office will please signify their wish by letter to the registrar at the College on or before Tuesday, May 19th, as it is necessary to include the names in the voting-papers which are forwarded to the Fellows, and no candidate is eligible unless his application is received within the date specified.

UNIVERSITY OF LONDON.—A course of eight lectures on the Structure and Functions of the Central Nervous System will be given in the physiological department of University College by Dr. W. Page May, Fellow and lecturer of the College, on Wednesdays, at 5 P.M., beginning on May 13th. The syllabus is as follows: (1) Recent Advances in Our Knowledge of Nerve Cells and Fibrils; (2) the Peripheral Nerves and Ganglia in their Relation to the Central Nervous System; (3) the Centres and Paths of the Spinal Cord; (4) Certain Points in the Brain Stem; (5) Recent Researches on the Cerebellum; (6) the Cerebral Cortex and Optic Thalamus; (7) the Afferent Paths of the Central Nervous System; and (8) the Efferent Paths of the Central Nervous System. These lectures are open to all students of the University of London, also to qualified medical men on presentation of their cards, and to such other persons as are specially admitted.

HYDROLOGY AND CLIMATOLOGY.—The Ninth Italian Congress of Hydrology and Climatology was held at San Remo from April 12th to 15th, under the presidency of Dr. U. Martemucci, at which Dr. Frederic Bagshawe of Hastings, chairman of council of the British Balneological and Climatological Society, was present as delegate of the society. Professor Maragliano of Genoa delivered an address on Sanatoriums for the Tuberculous in Relation to Public Health and gave the reasons why such institutions were not used along the Riviera. Very numerous papers followed, both in the morning and the afternoon. On April 14th the morning sitting was opened by a paper by Professor Vinai on the Treatment of Arterial Hypertension. Other papers and discussions followed. On the afternoon of the opening day a garden party and excursion took place at the golf links at Taggia, some three miles distant, which was largely attended. On the 14th the banquet of the association was held; it was attended by 125 members and many eloquent speeches were made. On the 15th a very enjoyable excursion took place to Bordighera, where a sumptuous luncheon was given by the hotel keepers at the Grand Hotel, Angst, to 120 guests, followed by a drive on the hills and a garden party given by Mr. Berry at the Villa Monteverde, and afterwards a drive to Ospedaletti, a sheltered bay between Bordighera and San Remo. A trip by steamer was arranged to Monte Carlo for the 16th. The whole of the proceedings passed off with great *éclat*.

Sir Samuel Wilks who underwent a somewhat serious operation upon May 1st is, we are glad to be able to state, progressing favourably.

Freemasonry.—Dr. Samuel West, F.R.C.P., and Dr. Charles Wells have had the honour of being appointed Grand Officers of the United Grand Lodge of England.

Presentation to a Medical Practitioner.—At the distribution of certificates to the Dartmouth corporation fire brigade class of the St. John Ambulance Association on April 25th Mr. John Henry Harris, M.D. Durh., M.R.C.S. Eng., L.S.A., was presented with a silver cigarette case as a mark of appreciation of his services as honorary instructor.

The Royal Sanitary Institute.—A discussion will be held in the Music Hall, Shrewsbury, on Saturday, May 23rd, at 11 A.M., on "The Inspection of Dairies and Cowsheds," which will be opened by Mr. T. W. H. Garstang, D.P.H., medical officer of health, Bucklow R.D.C., under the chairmanship of Colonel J. Lane Notter, R.A.M.C., deputy chairman of the council of the Institute. General discussion is invited. In the afternoon a visit will be made to the Shrewsbury Sewage Farm.

Donations and Bequests.—The late Mr. C. E. Gael, of Charlton Kings, Gloucestershire, has bequeathed £500 each to the Cheltenham General Hospital, the Delancey Fever Hospital, and the Cheltenham Eye, Throat, and Ear Hospital.—£2300 have been received already towards the fund for reducing the debt of the Royal Devon and Exeter Hospital. This includes £1000 from the late Mr. R. Wood of Sidmouth, £1000 from Mrs. Nosworthy of Dawlish, and £20 from Viscount Sidmouth.

The Medical Inspection of School Children.—In response to the desires of a number of school medical officers arrangements are being made for a short course of lectures and demonstrations to be given in London during Whit-week. Dr. James Kerr, Dr. H. Meredith Richards, Dr. C. J. Thomas, and other experienced medical inspectors have already promised to give addresses, and demonstrations of the details of actual medical inspection will also be arranged. School medical officers desiring to avail themselves of the course are requested to communicate with Mr. W. A. Lawton, at the offices of the Incorporated Society of Medical Officers of Health, 1, Upper Montague-street, Russell-square, London, W.C.

The Hertford General Infirmary and Dr. J. T. Tasker-Evans.—On April 30th a testimonial, which had been subscribed for by the governors and supporters of the Hertford General Infirmary, was presented to Dr. J. T. Tasker-Evans upon his retirement from the post of honorary medical officer after 29 years' service. The presentation took the shape of a silver tea and coffee service and silver electro-plated tray, with a cheque for 40 guineas, whilst a gold necklet was presented to Mrs. Tasker-Evans. It is worthy of note that during the course of the proceedings reference was made to a proposal to substitute for the name "Infirmary" the word "Hospital." Unfortunately, in the lay mind the name "Infirmary" is associated with Poor-law charity and it would no doubt be of great advantage to the institution in question if the name were changed as suggested.

Longevity.—The Rev. Thomas Lord, Congregational minister of Horncastle, Lincolnshire, has recently celebrated the hundredth anniversary of his birthday, having been born at Olney, Buckinghamshire, on April 22nd, 1808. Mr. Lord is said to take a two-mile walk every day. For 75 years he has been connected with the temperance movement and about a month ago he preached the Band of Hope anniversary sermons at Wainfleet. He has been married three times but is now a widower and resides with his daughter and son-in-law, Mr. and Mrs. C. M. Hodgett. He has been a life-long non-smoker.—Lord Gwydyr has recently completed his ninety-eighth year, having been born in 1810. He is High Steward of Ipswich, in the neighbourhood of which he resides, and was for many years chairman of the Suffolk quarter sessions. From 1833 to 1870 he was secretary to the Lord Great Chamberlain. He has one son who is himself a grandfather.

Royal Microscopical Society.—At a meeting of the Royal Microscopical Society held on April 15th a communication by Mr. J. Strachan on Dendritic Growths of Copper Oxide in Paper was read by Mr. Shillington Scales. Minute particles of copper were found in all kinds of paper, whether composed of linen, esparto grass, or wood pulp, and had no doubt been abraded from the paper-making machinery. The dendritic formation was due to partial solution of those particles and subsequent deposition of insoluble oxide. Mr. F. Enock delivered a lecture on Nature's Protection of Insect Life, illustrated by lantern slides taken by three-colour photography.

Medico-Psychological Association of Great Britain and Ireland.—The next general or quarterly meeting will be held at 11, Chandos-street, Cavendish-square, London, W., on Tuesday, May 19th, under the presidency of Dr. P. W. Macdonald, at 3 P.M. A paper and lantern demonstration on Some Points in the Histology of Lymphogenous and Hæmatogenous Toxic Lesions of the Spinal Cord will be given by Dr. David Orr and Dr. R. G. Rows. A discussion will be introduced by Dr. D. G. Thomson on the Teaching of Psychiatry. Members will afterwards dine together at the Café Monico, Piccadilly-circus, W., at 7 o'clock, when it is hoped that as many as possible will join. The price of the dinner, exclusive of wine, will be 7*s.* 6*d.* Evening dress optional.

The Chemists' Exhibition.—Once again this exhibition is being held in its old quarters at the Royal Horticultural Hall, Vincent-square, Westminster. The stalls are as attractively arranged as usual, and although perhaps there is no special novelty of a striking character shown yet on all sides are found exhibits that appeal not only to members of the drug and allied trades but also fulfil the useful function of bringing before the notice of members of the medical profession the many modifications in the methods of putting up some of the older drugs, whilst at the same time the exhibits illustrate by practical example many of the newer forms of medicaments. University of London.—A course of eight lectures on the Structure and Functions of the Central Nervous System will be given in the physiological department of University College by Dr. W. Page May, Fellow and lecturer of the College, on Wednesdays, at 5 P.M., beginning on May 13th. The syllabus is as follows: (1) Recent Advances in Our Knowledge of Nerve Cells and Fibrils; (2) the Peripheral Nerves and Ganglia in their Relation to the Central Nervous System; (3) the Centres and Paths of the Spinal Cord; (4) Certain Points in the Brain Stem; (5) Recent Researches on the Cerebellum; (6) the Cerebral Cortex and Optic Thalamus; (7) the Afferent Paths of the Central Nervous System; and (8) the Efferent Paths of the Central Nervous System. These lectures are open to all students of the University of London, also to qualified medical men on presentation of their cards, and to such other persons as are specially admitted.

Hydrology and Climatology.—The Ninth Italian Congress of Hydrology and Climatology was held at San Remo from April 12th to 15th, under the presidency of Dr. U. Martemucci, at which Dr. Frederic Bagshawe of Hastings, chairman of council of the British Balneological and Climatological Society, was present as delegate of the society. Professor Maragliano of Genoa delivered an address on Sanatoriums for the Tuberculous in Relation to Public Health and gave the reasons why such institutions were not used along the Riviera. Very numerous papers followed, both in the morning and the afternoon. On April 14th the morning sitting was opened by a paper by Professor Vinai on the Treatment of Arterial Hypertension. Other papers and discussions followed. On the afternoon of the opening day a garden party and excursion took place at the golf links at Taggia, some three miles distant, which was largely attended. On the 14th the banquet of the association was held; it was attended by 125 members and many eloquent speeches were made. On the 15th a very enjoyable excursion took place to Bordighera, where a sumptuous luncheon was given by the hotel keepers at the Grand Hotel, Angst, to 120 guests, followed by a drive on the hills and a garden party given by Mr. Berry at the Villa Monteverde, and afterwards a a poor person on the happening of any sudden illness, although no order has been given for the same by the guardians or any of their officers or by the overseers. Under this provision the guardians may pay the fee of any medical man called in on the advice of a midwife to attend a woman in childbirth in any case of difficulty. The Board is not empowered to alter this provision so as to make it compulsory. Under the regulations which are in force in most of the unions, however, it is compulsory on the guardians to pay a fee to a Poor-law medical officer who is called upon to attend a woman in childbirth by order of a person legally qualified to make the order. They must also pay the fee if in circumstances of difficulty or danger he visits without any order any such woman who is actually receiving relief or who the guardians may subsequently decide was in a destitute condition.

Medical Officers and Indian Jails.

Mr. Rees asked the Under Secretary of State for India whether he was aware that since the introduction of the new scale of pay for Indian Medical Service officers in charge of jails there were, at any rate in the Madras Presidency, uncovenanted officers of long service in charge of central jails who did the same administrative work as medical officers in charge of central jails, but who had not been placed on the same scale of pay for their administrative work; and would he consider whether this difference should be removed and these officers be put on the same scale of pay as medical officers in administrative charge of jails, in so far as administrative and not medical duties were concerned.—Mr. Buchanan replied (by written answer): The recent improvement of the pay of members of the Indian Medical Service in charge of jails was part of a general improvement of the pay of that service introduced with a view to making the service more attractive and securing more and better qualified recruits. The same considerations do not apply in the case of the officers referred to in the question who are not members of the Indian Medical Service and whose rates of pay are determined by the conditions of their own service. The Secretary of State does not, as at present advised, see sufficient reason to take any action in the matter, which is primarily one for the consideration of the Government of India.

The Belfast Health Commission.

Mr. Devlin asked the Chief Secretary to the Lord Lieutenant of Ireland what steps, if any, were being taken to give effect to the recommendations of the Belfast Health Commission.—Mr. Birrell forwarded the following written answer: The report of the Commission, which reached the Local Government Board on April 10th, is receiving the serious consideration of the Board which has forwarded copies to the Belfast corporation with a request that a special meeting of the corporation should be summoned to consider it.

TUESDAY, MAY 5TH.

Damages for a Death from Typhoid Fever.

Mr. Bottomley asked the President of the Local Government Board whether his attention had been called to a recent case in which the authorities of the Three Counties Asylum, in Bedfordshire, were sued by a Mrs. Brown, the widow of the bailiff of the Arlesey Asylum, for damages for the loss of her husband through typhoid fever, contracted owing to defective drainage, and had damages to the extent of £650 awarded against them; whether he was aware that the authorities were represented by three counsel and produced a number of eminent experts, involving a total expenditure in connexion with the proceedings of upwards of £3000; whether they were now proposing to appeal against the decision; and, if so, whether the Local Government Board would make any representation to them before further expenditure of public funds was incurred, especially in view of the fact that Mrs. Brown was a woman without means and quite unable to bear the expense of protracted legal proceedings.—Mr. Burns replied: I have made inquiry into this matter and I understand the facts to be generally as stated in the question. I do not know the precise amount of the costs incurred in the case. I regret the expenditure involved but I am assured that every care has been taken to avoid as far as possible any unnecessary expense. Three counsel were engaged for the visiting committee, partly because their leading counsel was unexpectedly occupied in another case, and partly because the plaintiff was also represented by three counsel. The visiting committee considers that the death of the plaintiff's husband was not attributable to typhoid fever contracted owing to defective drainage, and acting on the advice of its counsel it is moving the Court of Appeal for a new trial or for judgment for the defendant. It is expected that the appeal will be heard in the course of the next few days. I have no jurisdiction which would enable me to interfere with the discretion of the visiting committee in the matter.

Typhoid Fever and Impure Water.

Mr. Bottomley asked the President of the Local Government Board whether he could state the average annual number of deaths recorded as due to typhoid fever and other diseases contracted through drinking impure water.—Mr. Burns answered: I am not aware of any records which would give the information desired.

Legislation on Milk-supply.

Mr. Courthope asked the President of the Local Government Board when the Bill dealing with the milk-supply would be introduced.—Mr. Burns said in reply: The Bill is in preparation, but I cannot at present say when it will be introduced.

Deaths under Anæsthetics.

Mr. Bramsdon asked the Prime Minister whether his attention had been called to the large number of deaths that occurred annually from the effects of anæsthetics administered to patients who were about to undergo, or were undergoing, operations, or after such operations had been performed; whether he was aware that there was no official record of the number of deaths that really occurred during anæsthesia, partly because such deaths were sometimes certified as due to causes other than anæsthesia, and in that case were not reported to the coroner, and partly because notification was not followed by official inquiry; whether he was aware that those persons who administered anæsthetics were not necessarily specially trained to do so or always registered medical practitioners; and whether, having regard to the greater safety of the public and for the advance of scientific medicine, he would consider the advisability of securing a more accurate and comprehensive knowledge of all the facts connected with the administration of anæsthetics, whether fatal or non-fatal, by appointing a Royal Commission with advisory powers to investigate and report upon the whole question.—Mr. Gladstone answered: My right honourable friend has asked me to answer this question. I have not yet completed the inquiries referred to in the answer I gave to my honourable friend on March 30th. I am not certain that a formal investigation is either necessary or desirable, but the matter is receiving careful consideration.

OOKS, ETC., RECEIVED.

Office of the Superintendent of Government Printing, India, Calcutta.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. The Development of the Leishman-Donovan Parasite in Cimex Rotundatus. Second Report. By Captain W. S. Patton, M.B., I.M.S. (on Special Duty). New Series. No. 31. Price Rupee 1, or 1*s.* 6*d.*

Rebman, Limited, 129, Shaftesbury-avenue, London, W.C.

Hematological Atlas. With a Description of the Technic of Blood Examination. By Priv. Doz. Dr. Karl Schleip, Scientific Assistant in the Medical Clinic, University of Freiburg i.B. Spezielle Diagnose der Inneren Krankheiten. Ein Handbuch für Aerzte und Studierende. Nach Vorlesungen bearbeitet von Dr. Wilhelm v. Leube, Professor der Mediz. Klinik und Oberarzt am Julinsspital in Würzburg. II. Band. Siebente vollständig umgearbeitete Auflage. Price M.16.

Die Lehre von der Intubation. Von Prof. Dr. J. von Bókay, Direktor des "Stefanie" Kinderspitals zu Budapest, Ehrenmitglied der "Moskauer kinderärztlichen Gesellschaft," korrespondierendes Mitglied der "Société de Pédiatrie" in Paris und der "Aerztlichen Akademie" in Rom. Price M.10.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Carlyle, Oliver, L.R.C.P. & S. Edin., has been appointed House Surgeon to Salford Royal Hospital.

Carstairs, J. Lindley, M.B., C.M. Glasg., has been appointed Assistant Obstetric Physician to the Maternity and Women's Hospital, Glasgow.

Chapman, J. S., M.B., B.S. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Turriff District of the county of Aberdeen.

Johnston, D. J. G., M.B., B.S. Aberd., has been appointed Assistant Medical Officer of Health of Ipswich.

Mathieson, D. Morley, M.B., Ch.B. Edin., D.P.H., has been appointed School Medical Officer and Assistant Medical Officer of Health of the City and County of Norwich.

Scott, James, M.B., Ch.B. Edin., has been appointed Senior House Surgeon at the Bolton Infirmary and Dispensary.

Stamp, William Daniel, M.R.C.S., L.R.C.P., L.M. Edin., has been appointed Deputy Medical Officer to the Workhouse and Northern District by the Plympton St. Mary (Devon) Board of Guardians.

Stirk, Percy Herbert, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Inspector of Schools by the Exeter Education Committee.

Wilmot, E. Darwin, M.B., Ch.B. Edin., has been appointed Junior House Surgeon at the Bolton Infirmary and Dispensary.

Wright, O. Kentish, M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer to the City of Nottingham Isolation Hospital.

be prescribed by an Order of His Majesty in Council as in this Act provided." He explained that there had been a divergence of opinion on this matter and that another scheme for the registration of nurses was in the field. He argued that it was impossible in the present state of public opinion to have a register of nurses analogous to the Medical and Dental Registers and that there should be penalties on those who not being on the register practised as nurses.

Lord AMPTHILL moved the rejection of the Bill on the ground that its provisions were opposed by the medical and nursing professions. A movement was initiated 20 years ago to obtain State registration of nurses and that had received the assent of the whole medical profession and the great body of nurses. The principle of State registration was approved of by the General Medical Council and the British Medical Association. Lord Balfour's Bill did not provide for a proper standard of training. It did not provide proper representation of the nurses and the medical profession. Its promoters had deliberately refrained from getting the views of the professions concerned. Its object was to put an obstacle in the path of legislation on the principles laid down by a Select Committee of the House of Commons and embodied in a Bill now before that branch of the Legislature.

The Earl of CREWE (speaking after considerable discussion had taken place) said that the question involved was not so simple as might appear. It might be a question of Lord Balfour's Bill or nothing at all. The passage of a Registration Bill was by no means so easy as Lord Ampthill and others might have the House believe. As Lord President he had had two difficulties brought before him. One referred to machinery, and it was difficult to get over. The medical profession on the one hand and the nursing profession on the other insisted that its profession must have the majority on the council which would be formed. That was a difficulty which, so far as he knew, had been by no means solved. There was another difficulty. How were they to provide registration as a guarantee of permanent efficiency? He was heartily in favour of the principle of registration, but he did not see a prospect of any Registration Act being passed within the next few years, not merely on account of Parliamentary difficulties but also on account of the inherent difficulties which he had mentioned. He regarded Lord Balfour's Bill as a step in advance and he could not see that it was an obstacle to registration in the future. He would vote for the second reading.

After further discussion the House divided when there voted:

For the rejection	53
Against	20
Majority for rejection	33

The Bill was accordingly rejected.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 29TH.

The Cost of Medical Inspection of Schools.

Mr. PIKE PEASE asked the President of the Board of Education whether he would lay upon the table an authorised copy of his recent statement as to the costs of medical inspection in elementary schools.—Mr. RUNCIMAN answered: I think the only point of public interest in the statement to which the hon. Member refers was to the effect that at a time when the amalgamation of the existing grants is to be undertaken, the Government could not propose a special grant for medical inspection or any increase in exchequer aid towards the expenses of local education authorities under the Elementary Education Acts in anticipation of the additional sum to be provided in connexion with the Education Bill now before Parliament.

The Law Relating to Coroners.

Sir WILLIAM COLLINS asked the Secretary of State for the Home Department whether, in connexion with the proposed reforms in the law relating to coroners, he would have regard to the representations made to the Lord Chancellor on this subject in March, 1907, by the Medico-Legal Society and by the London County Council.—Mr. H. SAMUEL (for Mr. GLADSTONE) said in reply: My honourable friend will be aware that the subject of death certificates was fully dealt with by a Select Committee of the House of Commons which reported in 1893 and that the proposals to which he refers are substantially covered by the Committee's recommendations. The Secretary of State has under consideration, as has already been announced, the question of appointing a Departmental Committee to inquire into certain points relating to coroner's inquests and so far as the proposed reforms affect coroners they would come within its scope and form part of its investigation.

The Sale and Inspection of Foreign Milk.

Mr. JESSE COLLINGS asked the President of the Local Government Board whether in the Bill he proposed to bring forward with regard to milk-supply he could find means to provide that foreign fresh milk should not be sold in this country unless it was produced under conditions or restrictions as regards sanitation at least equal to those to be imposed on British farmers and cowkeepers.—Mr. BURNS replied: I am afraid I cannot undertake to say beforehand what provisions will be contained in the Bill I propose to introduce with regard to milk-supply.

Mr. JESSE COLLINGS further asked the President of the Local Government Board whether he had seen the statement made at the meeting of the council of the British Dairy Farmers' Association to the effect that 578 hundredweights (6473 gallons) of fresh milk were imported into the United Kingdom during the nine weeks ending Feb. 1st, compared with only 15 hundredweights (168 gallons) during the corresponding period of last year; and, if the statement was correct, whether he would say what steps were being taken to examine the quality and condition of this imported milk.—Mr. BURNS answered: According to the figures which I have obtained from the Commissioners of Customs the quantity of fresh milk imported into the United Kingdom during the nine weeks ended Feb. 1st, 1908, and during those ended Feb. 2nd, 1907, was 499 hundredweights and 94 hundredweights respectively. Samples of imported milk, as of any other milk, may be taken under the Sale of Food and Drugs Acts with a view to their being analysed and dealt with under those Acts. Moreover, samples of imported milk are from time to time taken by the officers of Customs and sent to the Government laboratory under the same Acts. If adulteration is discovered the cases are reported to the Commissioners, who institute legal proceedings where this seems to them desirable. Further, I am arranging to have some samples of imported milk examined as to bacterial contamination and the presence of dirt.

Temperance Drinks and Mortality.

Mr. BOTTOMLEY asked the Secretary of State for the Home Department whether he would grant a return showing the relative mortality of persons engaged in the manufacture of ginger-beer, lemonade, soda-water, and other aerated drinks as compared with those engaged in breweries and public-houses.—Mr. BURNS (who replied) said: I am afraid I could not assent to the proposed return. I have communicated with the Registrar-General with regard to it and I find that his records do not show separately the mortality of the persons engaged in the manufacture of aerated drinks. Consequently great labour and expense will be involved in getting the particulars necessary for arriving at this mortality. I may add that the number of persons engaged in the manufacture of aerated drinks is too small to afford a basis for trustworthy statistics. The total number of males between the ages of 25 and 65 who were so employed in England and Wales, according to the Census of 1901, was only 5587.

THURSDAY, APRIL 30TH.

The Sanitation of Whaling Stations.

Mr. CATHCART WASON asked the Secretary for Scotland what steps the Fishery Board for Scotland was taking to insist that sanitation and cleanliness should be rigorously carried out at the whaling stations and especially if masses of decaying matter would be consumed by fire or chemicals and not allowed to float about the voes, destroying the mussel beds and gravely injuring the homes of the people.—Mr. SINCLAIR replied: The duty of seeing that these stations are kept in a sanitary condition is primarily a matter for the local authority and their officers and in the event of their default it would be the duty of the Local Government Board to interfere. I may add that the by-laws framed by the local authorities for regulating the business carried on at these stations provide for the prevention of offensive material being deposited in, or allowed to escape into, the sea.

Telephone Receivers and Health.

Sir EDWARD SASSOON asked the Postmaster General whether he was aware that no restrictions existed in France as regards the choice of telephone instruments; and, in view of the danger to health involved in the use of receivers insisted upon by the Telephone Company, whether he would take steps to allow the public the same freedom of selection as is allowed in France.—Mr. BUXTON said in reply: Telephone subscribers in France are required to purchase their own telephone instruments and hence their choice is not restricted. The consequent lack of uniformity of apparatus and the great number of cheap and often inefficient instruments in use constitute one of the causes alleged for defects in the French telephone service, and I do not think that a satisfactory telephone service could be carried on in this country under such conditions. I am assured that there is no danger to health arising from the types of telephone officially provided in the United Kingdom.

Scarlet Fever at Tidworth Barracks.

Captain FABER asked the Secretary of State for War whether he could state how many cases of scarlet fever there were at present in the barracks at Tidworth, and whether the cases had been isolated; and, if not, what hospital they were in.—Mr. HALDANE (by written answer) replied: Four cases of scarlet fever had occurred at Tidworth. The cases are being treated at the isolation hospital, Bulford.

MONDAY, MAY 4TH.

National Sleeping Sickness Bureau.

Mr. REES asked the Under Secretary of State for the Colonies whether the Government had decided to establish a national sleeping sickness bureau with headquarters in London; whether a convention between Great Britain and Germany for the prevention of the spread of this malady was contemplated; and whether he could give the House any information on this subject.—Colonel SEELY replied: The answer to the first two portions of my honourable friend's question is in the affirmative. The Secretary of State hopes to be in a position to publish detailed information regarding the bureau shortly.

The Sale of Disinfectants.

Mr. REES asked the honourable Member for South Somerset, as representing the President of the Board of Agriculture, whether the Board had made an order to the effect that disinfectants, weed killers, and the like preparations were drugs within the meaning of the Sale of Food and Drugs Act; and whether it was proposed that such disinfectants, weed killers, &c., if sold by others than registered pharmacists, should have a label attached declaring their efficiency in terms of certain recognised standard tests.—Mr. J. A. PEASE answered (on behalf of Sir E. Strachey): The reply to the first part of the question is in the negative. The conditions under which the articles to which my honourable friend refers should be sold are under consideration by the Joint Committee appointed in connexion with the Poisons and Pharmacy Bill.

The Status of the President of the Local Government Board.

Mr. HAROLD COX asked the Prime Minister whether it was proposed to increase the salaries of the President of the Board of Trade and of the President of the Local Government Board; and, if so, whether this increase would be provided by a reduction of other Ministerial salaries or by increasing the burdens upon the taxpayer; and, in the latter alternative, when he proposed to ask the House to make the necessary grant.—Mr. ASQUITH said in reply: The whole question of the functions and status of these two offices is the subject of inquiry by a committee of the Cabinet, and I am not at present able to say what proposals we shall be in a position to make to Parliament.

The Confinement of Poor Women.

Mr. EUGENE WASON asked the President of the Local Government Board whether he was aware that valuable lives of poor women were sometimes sacrificed in their confinement through the absence of a medical man, owing to their inability to pay the fee for his attendance; and whether the Local Government Board would so far vary its circular of July 29th last to the boards of guardians on the Midwives Act of 1902 as to make the payment of the medical man's fee compulsory by the guardians instead of permissive, as at present.—Mr. BURNS answered: The guardians are authorised by the Poor-law Amendment Act, 1848, to pay for any medical assistance rendered to

Notes, Short Comments, and Answers to Correspondents.

SOME MEDICAL MATTERS ILLUSTRATED UPON ANCIENT EGYPTIAN MONUMENTS.

A MAGNIFICENT Egyptological work entitled "Une Rue de Tombeaux à Saqqarah," just published by M. Jean Capart, conservator of the Egyptian collection in the Brussels Museum, in two of the 107 photographs of sepulchre reliefs presents scenes of much interest to the medical profession. One of these plates, No. 41, gives a clearly carved portrait figure of one of those steatopygous dwarfs whom we know the ancient Egyptians used to employ as dancers, and perhaps also as clowns, to amuse guests at entertainments and who are supposed to be identical with those imported slaves called Dangas whom their hieroglyphical inscriptions tell us they obtained from Southern Nubia.

The peculiar bodily form of these individuals associates them closely with the pygmies, though Professor Naville, a very great authority, thinks that the diminutive pygmies were distinct from the persons with marked steatopygia, considering the latter not so much as a race possessing this malformation but as individual members of this special physical type who occurred sporadically among tribes the majority of whose members were perhaps similar to the ordinary negro. The figure engraved upon the wall of a tomb at Saqqarah, photographed by M. Capart, is certainly intended as that of a native of Central Africa and of negroid affinity, because he is a tribute bearer and as his contribution carries an African ape upon his shoulder. The breast is so prominently shown that the figure may be intended for that of a female, but the abdomen is not so protuberant as in some of these ancient Egyptian figures. The buttocks, however, are so, and all the limbs are extremely large in girth although short, the legs especially being quite disproportionately so.

It is well known that the physical characteristics of this type of mankind were transferred to the figure of the extremely ancient Egyptian deity Bes, or Bess, and from him to the Hellenic Gorgoneion type of Hercules, and thence to Silenus who was connected with Priapus and other phallic deities. The figures of Bes are frequently of an ithyphallic character. Whether all specimens of such varieties of the human type upon Egyptian monuments represent persons who possessed such peculiarities from birth, or sometimes those who subsequently attained them through arrested development, or some disease peculiar to the negroid race, somewhat of the character of elephantiasis, is a matter for discussion. To arrive at a wise decision all monuments of people presenting such characteristics should be published together and any texts relating to them in the Egyptian records should also be edited with them.

The other photograph of a relief which is interesting to the medical profession is that depicting the circumcision of a youth. The operation is shown in two tableaux, probably separated by an interval of some days. In the first the patient is erect, whilst an assistant in his rear holds up his hands so as to cover his eyes, perhaps to prevent his seeing what is being done. The instrument with which the operator—apparently a priest—is about to cut the prepuce has an oval form but is divided into two parts by a central line down the longer axis, so that if with Professor Max Müller, the Egyptologist, we see in the blade a knife of silex it was secured in a handle. The hieroglyphic determinative for the word for circumcision was a semicircle, and M. Capart suggests that this is intended for the fragment of skin removed by the rite. The second act of the operation was evidently less painful, for the young man is not held by the attendant, and indeed places his hand caressingly upon the operator's head, who is furnished with a differently shaped instrument which is not very clearly shown, and says to the youth in the rubrical text: "This is to do you good." What he was doing is perhaps explained in the rest of the inscription which may be translated, "to clean, to shave, to anoint." The Egyptian word is often used in those senses in ancient Egyptian medical works, though Professor Max Müller renders it doctor, but the word for doctor, ordinarily at any rate, is quite differently spelled. Neither have we any text on monuments, or papyri, suggesting that medical men were employed for circumcising. The act belonged perhaps to the priests or embalmers, if not, as in our time in Eastern lands, to the barbers. M. Capart concludes his remarks upon the subject by quoting the signboard of a barber at Assouan to-day which asserts that the shopkeeper is a hair-cutter, "practises circumcision, cures minor venereal complaints, and regenerates the blood." M. Capart's book, which is published by Vromant of Brussels, may be obtained of H. Greuel and Co. of London.

ACUTE DELIRIOUS MANIA AND ACUTE MANIA.

To the Editor of THE LANCET.

SIR,—Are the essential differences between the above complaints known to all medical men? My experience of a recent case leads me to suppose that they are not known as widely as they should be. The best description of acute delirious mania that I know of may be found in "Quain's Dictionary of Medicine" in the article "Mania" by Dr. G. F. Blandford. The opening words of Dr. Blandford's article are: "Acute delirious mania or maniacal delirium—whichever we prefer to call it—is something quite distinct from that ordinarily known as acute mania. The *symptoms are much graver*, the course is briefer and more defined, and *the treatment of the one would be quite inappropriate to the other.*" (The italics are mine.) The essentials of the treatment of acute delirious mania (which may safely be undertaken in many private houses) are the procuring sleep as soon as possible (opium is inadmissible), feeding, and very skilful kindly nursing. It may be remarked in passing how often an ignorant nurse will irritate a mental case by "keeping the patient quiet" as she calls it. Any sudden movement of arm or leg is pounced upon and the bed-clothes are immediately tucked in. If the patient tries to get out of bed he is immediately forced back again. Any sufferer from nervous insomnia who has experienced the relief gained by pacing the room will sympathise with the instinctive desire of a sufferer from acute delirious mania to get up occasionally and move about. It is indeed a peculiarity of the complaint that the patient objects to lie on an ordinary bed, but *will* lie on a mattress on the floor. Again, in the important matter of feeding, a tactful nurse will coax the patient to take food which is otherwise refused. I have no statistics showing whether cases of acute delirious mania are on the increase, but if any medical man who reads this communication is not conversant with the differences which distinguish this disease from ordinary acute mania, he should get up the subject. Treatment suitable for the last-named disease may lead to a fatal issue if applied in a case of acute delirious mania.

I am, Sir, yours faithfully,

April 25th, 1908. EDWARD A. OPIE.

THE NEED FOR MORE MOTOR AMBULANCES.

AT a recent inquest held by Dr. F. J. Waldo at Southwark invidious comparisons were drawn between the steps taken for the provision of mechanically driven ambulances in the City and the want of them often experienced in London outside its limits. The authorities who govern the City were referred to in complimentary terms by the coroner as pioneers in many matters and the particular instance in which their public spirit was praised is one of increasing importance in view of the dangers of our streets and of our industrial life which cannot be said to have diminished in recent years. In the case before the jury the deceased had fallen under the wheels of a lorry in East-street, Walworth-road, and the policeman who wheeled him on a hand ambulance to Guy's Hospital, where he succumbed to his injuries, had taken half an hour in doing so. As in such cases life may sometimes be saved by surgical aid promptly applied, and in the rendering of which every minute is of importance, the subject is one to which coroners may usefully direct the attention of the public.

A COINCIDENCE IN INVENTION.

To the Editor of THE LANCET.

SIR,—As makers of Mr. Seymour Stritch's pessary which called forth Mr. Hughes R. Davies's courteous letter and Mr. Stritch's reply thereto under this heading (published in THE LANCET of March 14th and 28th), will you allow us to briefly explain that there are inadvertences in both?

There is an essential difference between these two instruments. In Mr. Davies's pessary he claims much for its permanent oscillatory movement through 75° to 90°, whereas Mr. Stritch instructed us that subsequent fixation of his uterine support upon its stem was essential, contending that, in the case for which he was seeking support, anything but absolute fixation would render the instrument imperfect as it would allow some measure of prolapse of the womb and perhaps of the bladder also. This necessary fixation is brought about by a mechanism which, as far as we can trace, is original.

Personally we knew of Mr. Davies's pessary, having procured them from time to time from the makers, Messrs. Krohne and Sesemann, and but for Mr. Stritch's express instructions as to fixation we should certainly have suggested to him a trial of Mr. Davies's instrument. The questions of giving fixation, or movement, will, we think, not be without interest, as any suggestion towards helping these troublesome cases is, in our experience, always welcomed by the profession. With Mr. Stritch's sanction we beg you to favour us by publishing this explanation.

We are, Sir, yours faithfully,

April 28th, 1908. DOWN BROS., LTD.

POST-GRADUATE STUDY.

IN answer to our correspondent "Equator" we think that he would find he could do more post-graduate work in surgery in this country than he could on the continent, though possibly the arrangements here are not so convenient as those at continental centres where they make more arrangements for "six-week courses" than is the custom in this country. Our correspondent might apply to the Post-Graduate Association, Examination Hall, Victoria Embankment, London, W.C., which includes a number of general and special hospitals, to the Medical Graduates' College and Polyclinic, 22, Chenies-street, Gower-street, W.C., to the West London Post-Graduate College, West London Hospital, and to the hospitals of the Seamen's Society (address, the Secretary, Seamen's Hospital, Greenwich, S.E.). There are also various post-graduate classes held in different provincial centres such as Birmingham, Liverpool, Manchester, and others. In Scotland,

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BANGOR, CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House Surgeon. Salary £80 per annum, with board, washing, and lodging.

BENENDEN SANATORIUM.—Medical Superintendent. Salary £250 per annum, with board, lodging, and attendance.

BIRMINGHAM, EAR AND THROAT HOSPITAL, Edmund-street.—House Surgeon. Salary at rate of £70 per annum.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, May 7th, 1908.

During the week marked copies of the following newspapers have been received:—*Sanitary Record, Standard, Yorkshire Daily Post, Newcastle Chronicle, Liverpool Courier, Hereford Times, Yorkshire Daily Observer, Nottingham Press, Wimbledon Gazette, Wimbledon Boro' News, Broad Arrow, Glasgow News, Yorkshire Evening News, Manchester Chronicle, Reading Mercury and Oxford Gazette, Literary Digest (New York), &c.*

Edinburgh and Glasgow have elaborate post-graduate courses. The post-graduate courses at various continental centres such as Paris, Berlin, Vienna, Milan, and Budapest were described in volume ii. of THE LANCET of 1903, and in THE LANCET of Sept. 21st, 1907, a correspondent wrote to us saying how much he had been impresssed by the post-graduate course at Hamburg. Two courses are held at the hospitals yearly, the one generally in March and the other generally in August.

PLOMBIÈRES AND COLITIS.

To the Editor of THE LANCET.

SIR,—I should be grateful if any of your readers would give me information as to the "colitis cure" at Plombières and the cost of living, &c., at that place during the season.

I am, Sir, yours faithfully,

April 30th, 1908. ENQUIRER.

DELAYED SPEECH.

A MEDICAL man writes: "I have had brought to my notice the case of *an infant of two years and a quarter old who manifests no desire to speak. The child is quite intelligent,* not deaf, well-grown, and good looking. I should be obliged for any information or for reference to any literature bearing on the subject."

RAILWAY MEN AND SAFETY APPLIANCES.

A CORRESPONDENT calls our attention to the delay in the introduction of automatic couplings upon British railways, and generally to the subject of unnecessary accidents happening to railway servants owing to lack of mechanical appliances to minimise the risks inherent to their employment. He mentions that on the continent delegates representing various State and private railways meet annually at Berne with a view to standardising the equipment of their rolling-stock and to the obtaining of safety for those employed upon their lines, and he reminds us that Mr. Lloyd George, who appointed in 1906 a Railway Safety Appliance Committee, now leaves the carrying out of steps which he has initiated to his successor, Mr. Winston Churchill. The matter is, no doubt, one of great importance both to the men who have ample means of making known through their organisations any opinions as to which they are unanimous and to their employers who have to consider the financial and other aspects of all changes proposed.

◆

Dr. C. Ormerod.—The treatment in question is the usual quack formula: no medical opinion upon its utility can be forthcoming as long as its constitution remains a secret. Correspondence in our columns shows that the claims made for the treatment are unsubstantiated, as might have been expected.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Stephen Paget, H. F. Waterhouse): at 5.30 P.M.

Papers:

Mr. J. Crawford Renton: Sciatica and its Surgical Treatment.

Mr. F. C. Wallis and Dr. W. Ironside Bruce: The Treatment of *Ulcerative Proctitis by Zinc Kataphoresis.*

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—H. Beckett-Overy, W. J. Gow): at 7.45 P.M.

Paper:

Dr. R. H. Paramore: *The Supports of the Female Pelvic* Viscera.

N.B.—This paper will not be read but an abstract will be given and a discussion will take place in which leading anatomists and gynæcologists have already promised to take part.

Copies of this paper are now ready and can be obtained from the Secretaries, 20, Hanover-square.

Specimens:

Dr. Nepean Longridge: Visceral Hæmorrhages in New-born Infants.

Dr. Herbert Williamson: Womb-stone (sent by Dr. Preston Maxwell, China).

Mr. J. Bland-Sutton: (1) Two Examples of the Encapsulation of Sterile Fluid in connexion with the Fallopian Tubes and the Ovary; (2) Sarcoma of the Uterus.

Mr. J. D. Malcolm: A Malignant Ovarian Tumour and Part of a Malignant Sigmoid Flexure removed by Operation.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

ELECTRO-THERAPEUTICAL SECTION.—The next meeting will take place on May 22nd in the Rooms of the Royal Philosophical Society, Glasgow. Members who wish to attend and who desire to avail themselves of local hospitality should communicate with Dr. Reginald Morton, honorary secretary, in order that the necessary arrangements may be made in good time.

The Hunterian Lectures

ON

THE CONNECTIVE TISSUE IN CARCINOMA AND IN CERTAIN INFLAMMATORY STATES THAT PRECEDE ITS ONSET.

Delivered before the Royal College of Surgeons of England on Feb. 17th, 19th, and 21st, 1908,

BY VICTOR BONNEY, M.S., M.D., B.SC. LOND., F.R.C.S. ENG., M.R.C.P. LOND.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND; EMDEN RESEARCH SCHOLAR, MIDDLESEX HOSPITAL CANCER INVESTIGATION DEPARTMENT; LECTURER ON PRACTICAL MIDWIFERY, MIDDLESEX HOSPITAL; AND SURGEON TO OUT-PATIENTS AT THE CHELSEA HOSPITAL FOR WOMEN.

LECTURE I.

Delivered on Feb. 17th.

MR. PRESIDENT AND GENTLEMEN,—The degree of importance attaching to the changes manifested by the connective tissue in relation with carcinoma has been variously estimated by different observers. Waldeyer[1] laid great stress on them and distinguished two phases—namely, the "introducing" changes which he believed play an important rôle in the etiology of the growth and the "accompanying" change which determined its anatomical structure. In regard to the first of these he remarked that evidence of old connective tissue change is obtainable at the sites of most carcinomata. It is of the nature of an interstitial induration often preceding the malignant growth by many years. There is an increased vascularisation leading to proliferation of the epithelium, the cells of which subsequently become broken up into groups by invading wander-cells from the connective tissue. This epithelial isolation he regarded as the first step in the development of carcinoma. He thus stated all the essentials of the theory subsequently promulgated by Ribbert, and his conception of the importance of the connective tissue changes is best expressed in his own words: "I do declare now most decidedly that if any kind of tumours have as regards their etiology and mode of development any relation to inflammatory processes 'tis the carcinomata."

Ribbert[2] examining early cases of carcinoma of the skin noted that in all of them previous changes in the connective tissue could be distinguished. These consisted of a new tissue due to cell-proliferation which developed between the elastica and the epithelium, and the site of the carcinoma to be was therefore elevated. The proliferated connective tissue cells subsequently invaded the tips of the interpapillar processes, and separated the individual cells, which detached from the main mass acquired an independent power of proliferation, whereby they in their turn invaded the altered connective tissue. Subsequent investigation of carcinomata in other situations appeared to him to confirm these observations. He particularly pointed out that the elongated interepithelial or interglandular papillæ seen at the edge of a carcinoma were in their earliest inception not due solely to epithelial proliferation, since the apices of the elongated epithelial processes or glands bore a normal relation to the cutis vera or submucosa. The carcinomatous surface area according to him enlarges by successive conversion of non-malignant epithelium until the entire precarcinomatous area is used up. After this growth continues by the continued proliferation of the malignant cells already formed, but there is no new conversion. Ribbert's views have been supported by Borrmann[3] who has made an exhaustive study of carcinomata of the skin. In every case examined by him changes in the connective tissue had preceeded the onset of the growth. On the other hand he considers that an actual invasion of the epithelial cells by the connective tissue is rare, and believes that the germinal areas of a carcinoma are to be regarded as cell-complexes isolated in embryonic life. Ribbert in his latest publication has partly adopted the views of Borrmann, that is to say he believes that the initial process as far as the epithelium is concerned may be in some cases due to a developmental lesion, but whether it be due to this or to the changes wrought by inflammation the foundations of cancerous development are only laid when there has formed a new layer of tissue under the epithelium akin to granulation tissue, by means of which the physiological inter-relationship and inter-dependence that exist between the epithelium and its subjacent connective tissues are lost.

In contrast to the views of Waldeyer and Ribbert, von Hansemann[4] holds that the primary change in carcinoma is an anaplasia of the epithelial cell itself characterised by a new type of mitotic division, an independency of growth, and a power of limitless proliferation. He states that connective tissue cell proliferation does not necessarily occur round a carcinoma though it is usually present, and he noted that the stroma of metastases was often quite different to that of the primary growth. He attributes this to the nature of the tissue in which the growth is taking place and the varying pathological processes to which the stroma is liable. According to him the connective tissue changes are entirely secondary to the epithelial infiltration. His views have been supported by Hauser[5] and Heidemann.[6]

Max Borst[7] says that in early carcinomata changes of an inflammatory nature are always present. A real proliferation of the connective tissues is much less frequent. Whilst regarding these changes as largely reactive, he admits that they are also in some cases the special cause of the new growth. It is true, he says, that the interepithelial papillæ are elongated by proliferation, but the epithelial processes are more than correspondingly elongated and they must therefore be proliferating also. True isolation of epithelial cells such as described by Ribbert is a rare occurrence. The primary stroma is either composed of the pre-existing cells and tissues or is newly formed, as in the papillary and villous carcinomata. The stroma of metastases varies according to the tissue in which the metastasis is growing; on the whole it resembles that of the primary growth. Borst, therefore, appears to hold views intermediate between those of Waldeyer and Ribbert on the one hand and von Hansemann on the other—i.e., he allots to both epithelium and connective tissue a primary share in the process. He states that the cell infiltration and proliferation at the edge of a carcinoma is harmful and that it prepares the way for its further extension.

Fischer[8] endeavoured to produce in the subepithelial tissue of a rabbit's ear changes in the connective tissue comparable to those described by Ribbert in human carcinoma. After trying many substances he found that the repeated injection of a solution of the stain Scharlach R in olive oil produced not only an increase in the number of connective-tissue cells but also led to great epithelial hypertrophy terminating in definite downgrowth. The epithelial cells exhibited abnormal mitoses. According to him the connective tissue changes were not the cause of the epithelial proliferation but were coincident with it, and he attributed it to the effect of an "attraxin" contained in the Scharlach oil. The process, however, stopped short of malignancy and he pointed out that some additional factor was required to produce a carcinoma. His paper is of great value and marks a distinct advance in the experimental investigation of the causes of carcinoma.

Wakelin-Barrett[9] has confirmed Fischer's work. He believes, however, that the subepithelial tissue changes are secondary to the epithelial ingrowth, since they did not occur when the Scharlach oil was injected into areas of connective tissue not adjacent to epithelium. He endeavoured to produce artificial metastases of the thickened epithelium by implanting grafts into various situations, but was unsuccessful.

Bashford and Murray[10] have shown that the stroma of mouse cancer is a product of the tissues of the host and is not derived from the implanted tissue. Their results are of importance as applied to the study of secondary nodules,

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapst, Asnières, Paris.

still they are seen in large and unmixed aggregations often at a very considerable distance from the growth. In the early specimens of carcinoma that I have examined they are already present in large quantities. They proliferate in rows, producing rifts in the previously homogeneous fibrous tissue which in time completely disappears. They appear to divide by amitosis chiefly, bi-nucleate cells being commonly seen, but mitoses are sometimes observed.

Origin.—The origin of these cells is very obscure. They are practically not present in normal tissues. There is no evidence that they are derived from lymphocytes. Indeed, if a lymphatic gland the seat of carcinomatous invasion be examined, it is noted that the plasma cells lie in the stroma of the gland towards and in its capsule and quite distinct from the lymphocytes. With regard to a possible origin from endothelial cells, it is difficult to believe that endothelial cells become converted into plasma cells in view of the very distinctive character of areas of endothelial proliferation. It is true that collections of plasma cells are frequently met with around small vessels and capillaries. But on close examination it will be found that an endothelial lining and two or three layers of endothelial cells intervene between them and the lumen of the vessel. Occasionally lymphatic channels may be seen whose walls appear to consist entirely of plasma cells, but it must be remembered that the finest ramifications of the lymphatic system do not possess an endothelial lining. Large aggregations of plasma cells frequently surround well-formed vessels, and Whitfield[11] has suggested that they may spring from the endothelium of the perivascular lymphatics. The theory of Grawitz, which states that in resting conditions of the connective tissue certain cells may become invisible, to become again visible when an appropriate stimulus causes them to proliferate, is most applicable to the origin of plasma cells. My own observations incline me to derive their origin from certain elongated small nuclei visible in resting connective tissue, and which differ from the nuclei of ordinary fixed connective-tissue cells in being smaller and more chromatic. If the periphery of an area of plasma-cell proliferation stained by my method be closely examined certain elongated streaks stained by the pyronin will be seen, and all gradations between them and fully formed plasma cells may be traced. Heidemann, who supports Grawitz' "slumber-cell" theory, has noted the same appearances in sections stained by saffranin. I originally used saffranin in my staining method and entirely corroborate him.

Fate.—I find no evidence that plasma cells undergo active destruction by the ingrowing epithelial cells. They retain their position in the stroma longer than the lymphocytes. The delicate processes uniting them to other plasma cells would prevent regression before the advancing growth. On the other hand, there are frequent appearances suggesting that these cells can become elongated to produce some of the cells of fibrous tissue. In the process of this elongation the cytoplasm loses its distinctive staining properties and the nucleus becomes hyaline and reticular. Thus it is probable that they, together with the fixed connective-tissue cells, constitute the framework of the stroma on which a collagenous deposit subsequently occurs. In the oldest portions of the stroma they, with all the other cells there, appear to undergo pressure atrophy.

Endothelial Cells.

The part played by endothelial cells in carcinoma appears to be small if one limits the term "endothelial" to those cells definitely lining blood and lymph channels. Endothelial proliferations are seen occasionally around small blood-vessels. There is no evidence that they metamorphose into any other type of cell, the cell mass remaining distinctively hyaline. (Fig. 1.)

Leucocytes.

Polynuclear leucocytes are very slightly in evidence in a carcinomatous area under uncomplicated conditions. In sections stained by Leishman's method a considerable number of them are seen within the hæmic capillaries, but diapedesis is unusual. In ulcerating growths, however, a considerable number may be seen outside the vessels, especially where the epithelium is degenerate, as in a cell nest. Here they may be aggregated in considerable quantity between the flattened epithelial cells. All these leucocytes exhibit fine eosinophile granules in their cytoplasm.

The Fixed Connective Tissue Cells.

On the assumptions (1) that normal connective tissue consists of a meshwork of branching fibres surrounding a number of irregular spaces in relation to which are seen hyaline nuclei, round or elongated in shape according to circumstances; and (2) that in inflammatory conditions this meshwork becomes largely obscured by the number of additional cells brought to or produced in the part, I believe that the fixed connective tissue cells play a relatively unimportant part in the tissue changes associated with carcinoma. (Fig. 1.) Certain of them probably give rise to plasma cells, as has been shown. For the rest, a certain slight increase in their number occurs and mitosis is observed occasionally. Their increase is most obvious in the papillomatous types of carcinoma, where an undoubted elevation of the connective tissue is present. It is to be noted, however, that even in this type of growth the vast bulk of the warty mass is due to enormous epithelial proliferation, whilst the interepithelial papillæ though abnormally elongated are also abnormally narrowed. They are seen best in the older parts of the stroma, for here they are not obscured by the cloud of plasma cells and lymphocytes which crowd the growing edge. They possess fine processes (fibroglia fibres) which anastomose and make up the characteristic retiform structure of the stroma. In the oldest parts of the stroma the nuclei appear to be undergoing a pressure atrophy so that fibres only are found here.

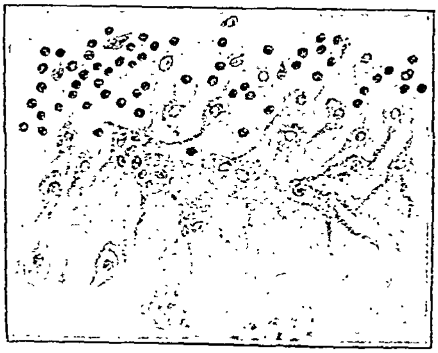
Mast Cells.

Mast cells are frequently to be observed in the neighbourhood of a carcinoma. On the other hand, they are present in normal tissues—as, for example, the breast, where large numbers of them can be found. I have not been able to satisfy myself that they are necessarily increased in number in a carcinomatous area. (Fig. 1.)

Giant Cells.

I have not been able to find giant cells of connective-tissue origin in the area of a carcinoma, though they have been described by Becher and others. Becher[12] stated that they were "foreign body cells" produced by the presence of degenerate or dead epithelium and that their presence indicated a tendency to natural cure. They must be rare, since I have not once seen them in the course of an examination of a very large number of specimens. Their absence in carcinoma is very striking, seeing the frequency with which they are met in association with necroses, foreign bodies, and experimental implantations—conditions in which a protective destruction of the offending substance is in progress. In experimental implantations of human carcinoma into rabbits that I have carried out these giant cells are very striking objects in the cell reaction which in a short time circumscribes the implanted tissue. They lie against and in the implanted tissue and are evidently destroying it. (Fig. 3.)

FIG. 3.



Edge of experimental implantation of human carcinoma into the peritoneal cavity of a rabbit showing histioclasis by giant cells.

The White Fibrous Tissue.

A study of white fibrous tissue, founded upon its formation in scars and its disintegration in inflammatory states, shows that it consists of a groundwork of fibrils to which the since mouse carcinoma grafts are to be regarded as experimental metastases.

---

[11] Journal of Dermatology, January, 1904.

[12] Virchow's Archiv, vol. clvi.

The literature bearing on the connective tissue changes in connexion with carcinoma is so large that this very brief *résumé* of the work and views of some of the principal investigators must suffice.

I shall now pass to my own work which is founded upon material from a large number of carcinomatous growths of various situations and from certain inflammatory states which commonly precede the onset of carcinoma. With this have been compared the normal histology of the tissues from the same parts together with the histological features characterising inflammatory processes not directly concerned in the production of carcinoma. I have specially studied the histology of very early carcinoma whenever such specimens have been available. In the course of this investigation I have made use of a large number of differential tissue stains, but I have particularly relied on three of them—namely, (1) Pappenheim's plasma cell stain; (2) Weigert's elastic tissue stain; and (3) my own triple stain, an account of which originally appeared in Vol. VI. of the Archives of the Middlesex Hospital, but which I subsequently modified in accordance with the description published at the last meeting of the Pathological Society of Great Britain and Ireland.

A GENERAL SURVEY OF THE CONNECTIVE TISSUE CHANGES IN PRIMARY CARCINOMATA.

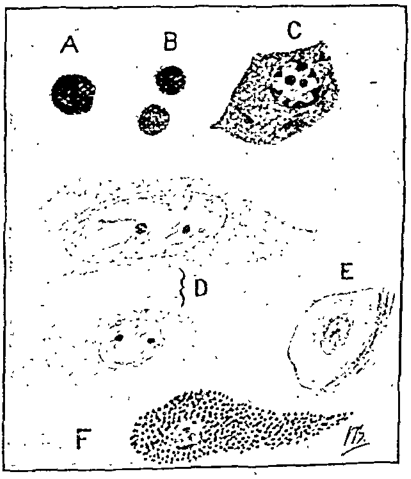
The Cellular Elements.

If the cloud of connective tissue cells surrounding an early primary carcinoma (the so-called zone of small round cell infiltration) be studied by the aid of differential stains it will be found that it contains a large number of cell types. These are as follows:—

The Lymphocytes.

Situation.—Lymphocytes are a conspicuous feature of the cell proliferation surrounding an early carcinoma. (Fig. 1.) They are especially aggregated at the tips of the epithelial processes, where they may be seen intercalating themselves between the individual epithelial cells. At the points of maximum aggregation, especially in squamous cell carcinoma, they invade the epithelial processes to such an extent that the epithelial edge becomes quite broken up and the demarcation between epithelial and connective tissue elements is obscured. As one passes into the older portions of the growth they become less numerous until in the oldest parts they may be absent altogether.

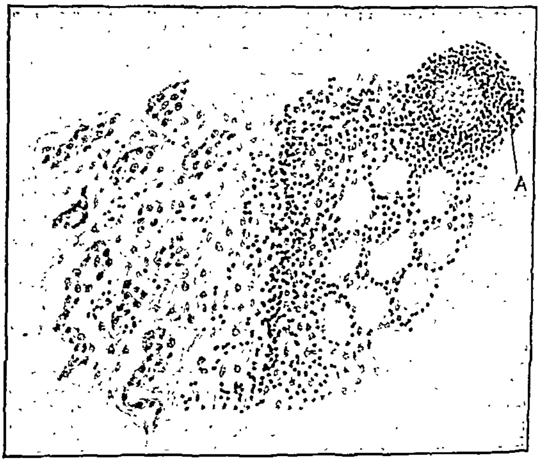
FIG. 1.



Principal cell types seen in the connective tissue in carcinoma. A, Lymphocyte. B, Lymphocytes exhibiting chromatic network. C, Plasma cell. D, Fixed tissue cells. E, Endothelial cell. F, Mast cell.

Origin.—The origin of these lymphocytal aggregations is very difficult to decide. As will be shown later their first appearance precedes that of the growth itself. Division either by mitosis or amitosis is never to be observed in them. They lie free within the spaces of the tissue network and I have been unable to find definite transitional forms between them and endothelial cells on the one hand or plasma cells on the other. If not formed by the tissues on the spot these cells must have been borne thither by the blood stream or have found their way along lymphatics. As regards the first, a certain number of lymphocytes are seen in the hæmic capillaries, but not in the quantity one would expect if their origin were solely from this source. They are much more numerously seen in the perivascular lymphatics, and it is by this route that most of them probably reach the site of the growth. It is also certain that the lymph glands in the vicinity of a carcinoma are in a state of enlargement and activity and that they contain big germinal areas containing many mitoses. Further, new lymph nodes appear in the tissues surrounding a carcinoma. Ribbert has laid stress on these and I have encountered them many times. That they are true nodes and not mere aggregations is proved by their exhibiting well-formed germinal areas with mitoses. (Fig. 2.)

FIG. 2.



Edge of a carcinoma of the breast showing at A a new lymph node with a well-marked germinal area.

Fate.—I find no evidence that these cells undergo destruction or metamorphosis during their contact with the epithelial cells. Certainly they take no part in the formation of the stroma of the growth. Contrasting their large numbers at the periphery of the growth with their sparsity in the older portion, it is strongly suggested that they are being pushed back by the advancing epithelial cells. If the lymphocytes retire from the tissue meshwork before the advancing epithelial cells it is possible that some of them are translated along the lymphatics to the next gland of the series and thus in part occasion the enlargement without epithelial invasion, which is seen in the glands at the periphery of a carcinomatous area.

It is noteworthy that in spite of the marked lymphocytosis in the area of the growth Pryce-Jones has shown that there is no increase in the mononuclear content of the blood at large until a very late stage of the disease and then only very slightly. Amongst these lymphocytes are seen some which when stained by my method exhibit a peculiar appearance. They are rather smaller than usual and present a fine black-coloured network within the substance of the nucleus. I am at present unable to state what is the significance of this but I have seen them in other inflammatory conditions. (Fig. 1.)

Plasma cells.

These cells are the most striking objects seen in the connective tissue in the neighbourhood of a carcinomatous growth. They present a large cell body, round or oval in form (unless subject to compression) with a round eccentric nucleus containing from five to eight peripherally placed masses of chromatin and one or two centrally placed nucleoli and they possess fine processes which unite them to other plasma cells. (Fig. 1.)

Situation.—They are rarely found in immediate contact with the epithelial cells and they never intercalate themselves between them, the zone immediately surrounding the epithelial cells being as a rule occupied by lymphocytes and endothelial cells only. The plasma cells lie beyond this zone and are mixed at first with lymphocytes, but further outside large as to suggest that some of it is newly formed. Moreover, it is granular and structureless, as Fischer pointed out. (Fig. 5.)

To sum up, then, elastic tissue disappears in all areas of connective tissue cell proliferation whether this be associated with a definite inflammatory state or with the connective tissue changes that are going on in a carcinomatous area. This disappearance is permanent—i.e., there is no regeneration of the elastic fibres when the cell proliferation has departed and fibrosis has supervened, which statement applies equally to the older parts of the stroma of primary carcinoma and the fibrotic stage of chronic granulomatous inflammation. In certain conditions, however, of chronic irritation which fall short of producing cell proliferation in the connective tissues, yellow elastic tissue may be increased by the deposition of a granular elastin around the old fibres. This is seen in some simple irritative states as well as in isolated areas in the stroma of carcinoma.

The Goulstonian Lectures

ON

THE INFLUENCE OF PREGNANCY UPON CERTAIN MEDICAL DISEASES, AND OF CERTAIN MEDICAL DISEASES UPON PREGNANCY.

Delivered before the Royal College of Physicians of London on March 17th, 19th, and 24th, 1908,

By HERBERT FRENCH, M.A., M.D. OXON., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO GUY'S HOSPITAL.

LECTURE III.[1]

Delivered on March 24th.

PREGNANCY IN RELATION TO CERTAIN FEVERS.

MR. PRESIDENT AND GENTLEMEN,—The next variety of cases that deserves consideration is that in which the mother, being at the time pregnant, develops one of the commoner fevers. Generally speaking, the pregnant state seems to confer some degree of immunity, the reverse being true of the puerperium. Scarlet fever, for example, shows less tendency to attack a pregnant woman than other persons equally exposed to the infection; whereas a woman who has been recently delivered of a child is particularly prone to take the disease if it is in the vicinity. Nevertheless, pregnancy confers no absolute immunity to the specific fevers, and should the patient contract one the question will arise as to what is likely to be the result both as regards the mother and as regards the child.

TYPHOID FEVER AND PREGNANCY.

Typhoid fever, for instance, may develop during pregnancy. There are a fair number of papers upon the subject, references to several of which have been given by Mr. H. T. Hicks and myself in THE LANCET.[2] The illness may begin at any period of the pregnancy and, like typhoid fever in England generally, it is less liable to develop in the summer months than it is in the autumn and winter.

The course of the disease is precisely similar to its course in others persons. Pregnancy does not seem to have any particular influence on the severity of the illness nor upon the prognosis as regards the mother. The death-rate will doubtless vary in different years; in our own cases it was 14 per cent., in Vinay's 17 per cent., and in Duyrot's 16 per cent., figures which do not differ widely from those given by the Metropolitan Asylums Board for all cases. The effect of enteric fever upon the pregnancy is, on the contrary, bad. In the majority of the cases abortion or premature labour takes place. This was the result in 85 per cent. of our cases, in 66 per cent. of Vinay's, in 63 per cent. of Martinet's, and in 65 per cent. of Penot's. The reasons for this high mortality amongst the children will be discussed below. Meanwhile it is right to mention, however, that it is quite possible in a minority of cases for the mother to pass through a typical and fairly severe attack of typhoid fever and yet for the pregnancy to continue to term and for the child to be born living and well. This was the case in one of our patients who developed typhoid fever in the fifth month of her pregnancy, recovered in due course, and was delivered at term of a healthy child who lived to grow up. There is no period of the fever at which a premature ending of the pregnancy seems more likely to occur than at another. The time at which it takes place depends rather upon the month of the pregnancy than upon the day of the fever. If the patient is already eight months pregnant, for example, delivery may occur during the first week or ten days after the onset of the fever; but if the pregnancy has not passed the fifth or sixth month it may continue into the third or fourth week of the fever and yet end prematurely. The mother seems to suffer remarkably little from the labour. Of course, she may already be in an extremely bad way from her typhoid fever, just as any other person might be, and then the prognosis is grave. It might have been expected that even if she had not hitherto been more than ordinarily ill from her enterica, the additional strain of labour must necessarily have made her considerably worse; this, however, is not the case as a rule. The delivery is most often easy and the patient experiences considerable relief. The uterus involutes just as if there were no maternal illness and the fever usually runs just the same course as if the incident had not occurred.

Transplacental Transmission of Toxins, Agglutinins, and Bacteria.

Several points of considerable scientific, if not clinical, interest arise in connexion with the child. The following questions might be asked. If the child were born dead during the course of typhoid fever in the mother, would it be likely that typhoid bacilli might be found in the fœtal tissues; in other words, can typhoid bacilli be transmitted directly from the mother to the fœtus? If the child's blood serum were tested by Widal's test, would it be likely to give a positive reaction? If so, does the fœtus produce its own agglutinins, or does it receive them ready formed from the mother? If the fœtus can and does become infected with typhoid bacilli, does it develop ulceration in the Peyer's patches of its intestine; in other words, can the macroscopic condition of the fœtal bowel be relied upon as a certain indication as to whether the fœtus is infected with typhoid organisms or not? If the fœtus becomes infected with typhoid bacilli, does this happen soon after the mother falls ill? and if not, how long after the mother's infection is that of the fœtus likely to occur? Would the child, if it lived, have a natural immunity to typhoid fever, supposing it had remained in utero until after the mother had recovered from her fever? If the fœtus is not affected in any of the above ways, or even if it is, are there any other lesions that it is likely to have suffered as the result of the mother's illness—lesions which may show their effects if the child lives and grows up?

It is only possible to give limited answers to some of these questions, and no answer at all to others; but it should some day be possible to give full answers if every case as it came under observation were fully investigated. The difficulty is that one does not always realise at the time the precise points to which attention should be particularly directed and the cases are sufficiently few and far between to make it difficult for a single individual to investigate any large number of them. Here, therefore, is another subject upon which a carefully directed collective inquiry would be good. The great point about typhoid fever in this respect is that it affords a natural experiment in human beings upon the placental transmission both of chemical substances—the agglutinins,—and of bacteria—the typhoid bacilli,—simultaneously.

Before entering upon the facts known in regard to the placental transmission of agglutinins and bacteria in typhoid fever itself it will be well to summarise shortly what is known about placental transmission generally. It seems clear, in the first place, that transmission might conceivably take place from mother to fœtus in one other way than through the placenta; it might occur viâ the liquor amnii. Ferrari[3] has shown this to be possible, materials being able to pass from the maternal lymphatics into the amniotic fluid, and thence, by being swallowed, into the alimentary term "fibroglia" has been well applied. These fibroglia fibres are prolongations of the fixed connective tissue cells which anastomosing with one another form a fine meshwork. Deposited around or on these is a collagenous matrix on which the density of the white fibrous tissue appears to depend. Thus in old scars it is present in large quantity, obscuring the cell elements and fibroglia fibres, whilst in all conditions of tissue rarefaction it disappears and the fibroglia fibres and fixed cells are unmasked. Such rarefaction due to disappearance of collagen occurs in all conditions of connective tissue cell aggregation. At the edge of a primary carcinomatous area this rarefaction of the tissues by the dense aggregations of lymphocytes and plasma cells is seen in progress (Fig. 4). The plasma cells in particular by their proliferation produce rifts in the previously homogeneous collagenous matrix, and this is occurring in many areas at a considerable distance from the growth. At the margin itself the fibrous elements become quite obscured by the cloud of lymphocytes and plasma cells. As one passes into the more central portions the cell aggregations (particularly the lymphocytes) disappear and unmask the decollagenised fibroglia fibres which with the hyaline fixed tissue cells and the elongated and atrophying plasma cells make up the stroma of the growth. The general effect is a characteristically loose and hyaline connective tissue staining ill with protoplasmic or nuclear stains and consisting, I believe, of altered plasma cells and the original fibroglia fibres and cells of the part from which all the collagenous material has been removed by the preceding cell proliferation. At a later stage still, and particularly in the slower growing forms of carcinoma, collagen is again deposited around the fibroglia fibres and the stroma becomes dense and, in appearance, almost acellular.

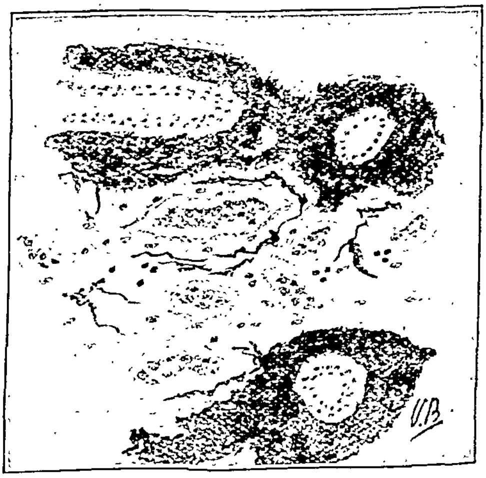
The Yellow Elastic Tissue.

Melnikow-Raswedenkow,[13] Abel,[14] and Goldmann[15] found that there occurred a progressive disappearance of elastic tissue in the stroma of carcinoma, and Wrench[16] in the laboratories of the Middlesex Hospital Cancer Investigation Department came to a similar conclusion. On the other hand, Fischer[17] found in certain areas of carcinoma of the breast large aggregations of a granular looking elastin whilst it was absent in other parts. He considered that these aggregations were due to a new formation. New formation of elastic tissue in malignant growths has also been reported by von Hansemann,[18] Lubarsch,[19] Polak-Daniels,[20] and Meinel. Tsutomu Inouye,[21] investigating 20 cases of gastric carcinoma, found that whilst generally speaking there was a disappearance of these fibres, yet here and there accumulations of them could be found which he regarded as of new formation. Tores[22] has described a new formation in fibrous tumours, whilst Melnikow-Raswedenkow and Williams proved it in certain inflammatory states (e.g., cirrhosis of the liver). These observations were confirmed by Wrench.

My own investigations show that in all areas of connective tissue cell proliferation there is a coincident disappearance of the elastic fibres. Thus they disappear early in tuberculous and syphilitic inflammation, in other chronic granulomatous processes and in the leukoplakias, nor does regeneration occur in the stage of scarring or fibrosis. Elastic tissue also disappears in certain conditions not associated with a marked proliferation of the tissue cells. Thus it is absent from the scars of healthy wounds, although as I shall show later there is little cell proliferation to be observed in the course of this process. Further, it tends to disappear in areas which have been frequently exposed to the action of x rays and it may undergo a simple pressure atrophy under the thickened epidermis of a corn. Lastly, a disappearance of it occurs in senile skin. Excluding the four last conditions, however, its absence from an area in which it normally occurs, unassociated with a present tissue cell proliferation, is a certain sign of old inflammatory change. In certain chronic irritative states, which, however, presumably fall short of producing a cell proliferation, its quantity may be actually increased. Thus under the skin of a lip which presented a hypertrophy of the epithelium, the result of chronic irritation, an abnormal quantity of granular looking elastin was found and I have noted similar appearances in the neighbourhood of several rodent ulcers.

In the area of primary carcinoma there has already occurred as I shall presently show a complete disappearance of yellow elastic tissue as a result of a pre-existent chronic inflammatory process. It is into this de-elasticised area that the first epithelial down-growths occur. Outside this area of previous disappearance a further destruction occurs by the plasma cell and lymphocytal proliferation which is going on beyond the limits of the epithelial cells. A few of the elastic fibres in this zone, however, escape destruction, and subsequently, as the growth progresses, come to lie in the stroma where they appear to be subject to a pressure atrophy and finally disappear, so that the oldest parts of the stroma contain no elastic tissue at all.

FIG. 5.



Carcinoma of the breast showing enormous aggregations of elastin. (Weigert's stain.)

It is, however, to be noted that in occasional specimens of carcinoma large aggregations of elastic tissue are present in isolated spots within the stroma. This is best seen in certain carcinomata of the breast, where they appear to surround the pre-existent ducts and large vessels which have become included in the growth but not destroyed by it. Though a certain amount of this elastic tissue may be due to condensation of previously existing fibres by the pressure of the epithelial masses, yet the quantity of elastin present is so from mothers who had suffered from, and survived, typhoid fever during the pregnancy. If even only one or two such children subsequently developed typhoid fever it would make it probable that none of them had an immunity, acquired either actively or passively in utero. It is a point that is not of any great clinical importance, because the number of living persons concerned is very small; but from a scientific point of view it would be of great interest to obtain an answer to the question, seeing that it bears upon the very complex subject of immunity and constitutes a natural experiment in man. It may, perhaps, be mentioned that the presence or absence of a positive Widal's reaction in the fœtus is by no means synonymous with the presence or absence of immunity to typhoid fever. The agglutinins upon which the Widal's test depends disappear rapidly from the blood after typhoid fever in the great majority of cases, as Dr. M. G. Louisson and myself[15] have shown. Acquired immunity to the disease does not disappear in this way. Consequently the fact that Widal's test is negative in a child born of a mother who has had typhoid fever during her pregnancy does not prove that the child is not immune to that disease. The longer before the child's birth the mother recovered from her illness the less likely would the infant's blood be to give a positive reaction, if one may argue by analogy with adults in whom the rapidity with which Widal's test, having been positive during the fever, becomes negative again a few weeks or months later is often remarkable.

Next comes the question as to whether or not the child, if it survives in spite of the mother having had typhoid fever during the pregnancy, is likely to suffer in other ways as it grows up. There is a considerable amount of evidence to show that this is very likely to be so, though it would be too much to say that it must be so. Professor Osler[16] has recorded a case in which the mother died from typhoid fever and the unborn child was found to have a large recent blood clot in its brain. Had the infant lived it must have exhibited the effects of this lesion which was apparently due to the mother's illness. Dr. Ballantyne[17] quotes numerous observers who have found "important pathological changes in the fœtal viscera, more particularly in the liver, thyroid gland, brain, and suprarenal capsules, which have a far-reaching effect upon the post-natal life of the offspring. ...... They consist in degenerative and sclerotic alterations unaccompanied by the presence of microbes, but productive of a slackening of body metabolism and lowering of body temperature, along with a tendency to develop broncho-pneumonia, gastro-enteritis, and infantile atrophy. The same results are produced by other infectious maternal conditions also and they are probably due to the transmission of toxic principles through the placenta. ...... It has been thought that typhoid fever of the mother in pregnancy may be the cause of intellectual peculiarities in her offspring developed many years afterwards."

The Question of advising Artificial Delivery.

Before leaving this subject there is one matter of great practical importance that arises from the question of fœtal infection and that is, At what period of the maternal typhoid fever does the fœtus become infected with typhoid bacilli? It is held by some bacteriologists that these bacilli are present in the maternal circulation from an early date in the illness, though it has by no means been established that this is an invariable rule. One would like to know precisely when typhoid bacilli are most numerous in the mother's blood, because that would be the time when the fœtus would be exposed to the greatest chance of bacterial infection. In our own case[18] the mother died upon the twenty-fourth day and the fœtus was not infected. In the cases recorded by others[19] of recent years—that is to say, since the methods of distinguishing the typhoid bacillus from the bacillus coli communis have been rendered more accurate than they formerly were—the examinations were made in five cases when the mother's illness was in its second or third week, and in none of these did the fœtal tissues yield typhoid bacilli, whereas in the three cases when the examination was made during the fourth or a later week of the mother's illness the organism was present in the child each time. This number of patients is too small to generalise from but the results seem to indicate that before the end of the third week of the mother's illness the child is much less likely to have become infected than it is in the fourth or a later week. It seems probable that the prognosis as regards the immediate and subsequent life of the child will be much better if the infant could be born before this bacterial infection occurs. If therefore the pregnancy has reached the time when the child is viable, and if for any reason it is much desired that a living child should be born, it would seem that the best advice for the physician to give would be that of obtaining obstetric assistance for bringing about delivery before the mother's illness had reached the end of the third week. This advice would not be necessary if the mother's interests alone were to be considered, for in her case the prognosis is not materially affected by allowing the pregnancy to take its own course; but if the child's life is a material consideration it would appear to be very risky to allow it to remain in utero beyond three weeks from the beginning of the typhoid fever. With each week of the fever the chances that the child will become infected with typhoid bacilli rapidly increase.

Other Specific Fevers in the Unborn Child.

The discussion upon typhoid fever in conjunction with pregnancy has been somewhat dwelt upon, because, owing to the comparative ease with which both typhoid bacilli and agglutinins can be looked for, the cases afford an admirable field for investigation; they constitute natural experiments in man upon the trans-placental transmission of disease upon which there is scope for much more work in future cases. Much might be said about the other specific fevers also but there is only room for a few words about each here.[20]

Small-pox has long been known to be transmissible from the mother to the fœtus in utero. It by no means follows, of course, that the child has the eruption in every case in which the mother suffers from the disease during her pregnancy. Sometimes the fœtus has died before the exanthem could appear upon it. Sometimes the child will be born quite healthy and catch the complaint at birth—a post-natal, and not an antenatal, infection. Sometimes when the mother has had variola early in her pregnancy the latter has continued to term and the child, though exhibiting no external evidence of having had small-pox, has been noted to possess a natural immunity to the disease in after life. In quite a number of cases, however, the child has been born with the typical eruption of small-pox upon it. The degree to which the infant is affected is very variable, bearing no direct relationship, apparently, to the severity of the disease in the mother. The stage of the eruption in the child may be almost identical with that in the mother, varying from vesicle to scar according to the length of time the pregnancy has continued after the mother was taken ill. It is noteworthy that the eruption goes through a pustular stage in the unborn child just as it does in an adult; and, as a rule, the size of each lesion is greater than that seen in grown-up people. On the other hand, the duration of the eruption on the skin of the child may apparently be much longer than it is in adults, for in Laurens's case,[21] quoted by Dr. Ballantyne, the mother had small-pox early in her pregnancy, and two and a half months later the premature infant was born still covered with the eruption. Dr. Allan Warner[22] records an interesting case of the same kind. The mother was taken ill with small-pox upon Jan. 8th when four months pregnant. The eruption appeared upon her on Jan. 11th; by the 23rd the crusts were falling off, and by Feb. 3rd she was quite free from all scabs. Pregnancy continued until the 15th when miscarriage occurred; twin female children were delivered, both being well covered with a typical small-pox eruption in the pustular stage.

Another very remarkable fact is that the father may have small-pox at the time of conception, the mother may show no sign of the disease, and yet her child may have it in utero—a point which seems directly analogous with some cases of congenital syphilis. This opens up a wide field for discussion but one upon which it is not possible to enter here.

Three further points may be briefly noticed. First, there seems to be no stage of fœtal life, from the third month onwards, at which the child may not be born with the eruption upon it. Secondly, even if there is no eruption upon the child's skin it is very possible that owing to the route of canal of the child. It is generally held, however, that the only path of fœtal infection that is at all common is that across the placenta. Dr. J. W. Ballantyne[4] points out how important this fact is in connexion with the site of the subsequent lesions, for the substances so transmitted reach the child by the blood-stream, and therefore if bacteria are conveyed to the unborn child they pass first the placenta, then the umbilical vein, then either the liver or the ductus venosus, then the heart, and so are distributed all over its body. The condition is thus one of general blood infection from the onset. The lesions may consequently be different in the child from what they are in the mother. As an illustration of this Bidone[5] records a case in which erysipelas in the mother gave rise to fungating endocarditis in the child.

In the second place, it is clear that the placenta allows chemical substances to pass across it from the maternal to the fœtal circulation; the nourishment of the child is thus conveyed.

In the third place, it is evident that a converse transmission of chemical substances takes place across the placenta from fœtus to mother; the child gets rid of the effete products of its metabolism in this way. It has been shown that quite abnormal substances may pass from fœtus to mother in a similar manner. Charrin[6] injected diphtheria toxin into animal fœtuses in utero, the mother dying from the toxæmia. It has been suggested that toxins elaborated by the fœtus and absorbed by the mother may be at the root of the herpes gestationis, the nephritis, and the tetany of pregnancy.

In the fourth place, even as regards chemical substances, the placenta can apparently exert some power of selection; that is to say, whereas some elements and compounds pass from the mother to the fœtus with comparative ease, others do so with much less readiness. Porak[7] performed a considerable number of experiments upon guinea-pigs in this connexion; and he found, for example, that whereas copper and lead were easily transmitted to the fœtal tissues arsenic passed across with greater difficulty, whilst mercury, though it reached the placenta and accumulated there, apparently passed no further. This feature of the placental functions has been termed its "barrier action."

Fifthly, this "barrier action" of the placenta, decidedly limited even in health, becomes still less marked when the mother is ill. Charrin and Duclert[8] showed that the presence in the maternal circulation of certain chemical substances or of various microbial toxins renders the placenta permeable to things which otherwise pass across it with difficulty; in other words, the placental barrier often breaks down when the mother is unwell, and things which would not be allowed to pass across to the fœtus if the mother were healthy are then able to do so.

Sixthly, it has been fully established that bacteria can pass from the mother to the fœtus *viâ* the placenta. There is a good deal of evidence to show that the placenta itself acts to some extent like a filter and that it may contain an abundance of bacteria before any have escaped past it to reach the fœtus. Consequently the fœtus seldom contains bacteria in anything like the numerical proportion that the mother's tissues do. Nevertheless, Küss[9] has shown in animals that tubercle bacilli may actually reach the fœtus from the mother *viâ* the placenta; and other observers[10] have demonstrated the same fact in regard to the bacilli of anthrax and of fowl cholera, the pneumococcus, the streptococcus, the meningococcus, the spirillum Obermeieri, and the bacillus of glanders.

It must be remembered, of course, that the experiments that have been made upon the subject have been upon animals; that the placentæ of different animals, varying as they do in size and thickness, vary also in the extent to which each exerts a barrier action against this substance or that; and that, therefore, the facts that have been found to be true of animals are not necessarily true of man. However, although the details may vary it is unlikely that the general principles taught by animal experiments do not apply to man. These principles are: (1) that abnormal chemical substances and toxins are able to pass from mother to child *viâ* the placenta; (2) that the placenta when healthy exerts some degree of "barrier action," allowing some things to pass less readily than others; (3) that this "barrier action" is not only imperfect but becomes less effective when the mother is ill; and (4) that not only substances in solution but also actual bacteria, even those of the size of anthrax bacilli, can reach the child from the mother.

To return now to the discussion of typhoid fever and the way in which the child is affected when the mother has the disease. It has been found repeatedly that the typhoid bacilli can cross the placenta, reach the child, and be recovered from the infant's tissues immediately after birth. There are, it is true, many cases in which the bacilli have been looked for and not found. This was so in the case investigated by Mr. Hicks and myself,[11] but negative evidence in many cases counts for little as compared with positive evidence in even only a few. Typhoid bacilli have been recovered from the tissues of the human fœtus by such observers as Fordyce, Freund and Levi, Etienne, Bolton, Eberth, Hildebrandt, Giglio, Durk, and Ernst.[12]

The fœtal blood-stream has been examined by Widal's test in a few cases, and although it has sometimes given no reaction in cases recorded by Fordyce, Chambrelent, Griffiths, Mosso and Danic, Bolton, and Kirton[13] it gave a positive Widal's test.

No answer can as yet be given to the question whether the fœtus produces its own agglutinins or receives them ready formed from the mother, but it would be a most interesting point to investigate further, especially if it could be shown that the fœtus did produce agglutinins for itself. There are at least two ways in which light could be thrown upon the question, neither of them very difficult provided they were kept in mind when an opportunity for using them arose.

First, in every case of maternal typhoid fever the child, if stillborn, should be thoroughly examined by cultural methods for typhoid bacilli, whilst at the same time its serum should be subjected to Widal's test. If several cases occurred in which the latter was positive whilst at the same time no typhoid bacilli could be obtained from any of the fœtal organs, it would tend to prove that the child could receive agglutinins ready-formed from the mother. Apparently no such case has yet been recorded; in every instance in which the child's blood serum gave a positive Widal's test bacilli were either shown to be present also or else they were not looked for.

Secondly, the precise degree of the Widal's reaction should be determined in all such cases both for the mother's and for the child's serum, with a view to ascertaining whether the child's blood will sometimes give a positive reaction in greater dilution than the mother's does. If, for example, a positive reaction were given by the child's serum diluted 500 times whilst the mother's serum failed to give it when diluted more than 200 times, it would be some evidence in favour of the agglutinins being formed, in part at least, by the child itself. These are points upon which observations are still required, and it is only now and then that an opportunity for making the investigation presents itself.

The next question—namely, whether a child that has become infected by typhoid bacilli in utero is likely to exhibit macroscopic evidence of this in the form of ulcerated Peyer's patches similar to those of adults suffering from typhoid fever—may be answered both yes or no. In a few cases, such as those recorded by Charcellay,[14] definite ulceration of the fœtal Peyer's patches has been noted. Such macroscopic lesions, however, are quite the exception, and the great majority of the children whose blood and organs have yielded typhoid bacilli on cultivation, or whose serum has given a positive Widal's test, have shown no such macroscopic lesions in the bowel. The absence of intestinal ulceration, therefore, is no proof that the child has not become infected by typhoid bacilli in utero. Consequently, it is essential to cultivate from the fœtal organs if it is desired to find out whether the fœtus has become infected from the mother or not.

The fourth question, as to whether the child, if it lived, would have a natural immunity to typhoid fever, is unanswerable at present. It would be possible to give an answer if a watch were kept upon all children born alive from mothers who had suffered from, and survived, typhoid fever during the pregnancy. If even only one or two such children subsequently developed typhoid fever it would make it probable that none of them had an immunity, acquired either actively or passively in utero. It is a point that is not of any great clinical importance, because the number of living persons concerned is very small; but from a scientific point of view it would be of great interest to obtain an answer to the question, seeing that it bears upon the very complex subject of immunity and constitutes a natural experiment in man. It may, perhaps, be mentioned that the presence or absence of a positive Widal's reaction in the fœtus is by no means synonymous with the presence or absence of immunity to typhoid fever. The agglutinins upon which the Widal's test depends disappear rapidly from the blood after typhoid fever in the great majority of cases, as Dr. M. G. Louisson and myself[15] have shown. Acquired immunity to the disease does not disappear in this way. Consequently the fact that Widal's test is negative in a child born of a mother who has had typhoid fever during her pregnancy does not prove that the child is not immune to that disease. The longer before the child's birth the mother recovered from her illness the less likely would the infant's blood be to give a positive reaction, if one may argue by analogy with adults in whom the rapidity with which Widal's test, having been positive during the fever, becomes negative again a few weeks or months later is often remarkable.

Next comes the question as to whether or not the child, if it survives in spite of the mother having had typhoid fever during the pregnancy, is likely to suffer in other ways as it grows up. There is a considerable amount of evidence to show that this is very likely to be so, though it would be too much to say that it must be so. Professor Osler[16] has recorded a case in which the mother died from typhoid fever and the unborn child was found to have a large recent blood clot in its brain. Had the infant lived it must have exhibited the effects of this lesion which was apparently due to the mother's illness. Dr. Ballantyne[17] quotes numerous observers who have found "important pathological changes in the fœtal viscera, more particularly in the liver, thyroid gland, brain, and suprarenal capsules, which have a far-reaching effect upon the post-natal life of the offspring. ...... They consist in degenerative and sclerotic alterations unaccompanied by the presence of microbes, but productive of a slackening of body metabolism and lowering of body temperature, along with a tendency to develop broncho-pneumonia, gastro-enteritis, and infantile atrophy. The same results are produced by other infectious maternal conditions also and they are probably due to the transmission of toxic principles through the placenta. ...... It has been thought that typhoid fever of the mother in pregnancy may be the cause of intellectual peculiarities in her offspring developed many years afterwards."

The Question of advising Artificial Delivery.

Before leaving this subject there is one matter of great practical importance that arises from the question of fœtal infection and that is, At what period of the maternal typhoid fever does the fœtus become infected with typhoid bacilli? It is held by some bacteriologists that these bacilli are present in the maternal circulation from an early date in the illness, though it has by no means been established that this is an invariable rule. One would like to know precisely when typhoid bacilli are most numerous in the mother's blood, because that would be the time when the fœtus would be exposed to the greatest chance of bacterial infection. In our own case[18] the mother died upon the twenty-fourth day and the fœtus was not infected. In the cases recorded by others[19] of recent years—that is to say, since the methods of distinguishing the typhoid bacillus from the bacillus coli communis have been rendered more accurate than they formerly were—the examinations were made in five cases when the mother's illness was in its second or third week, and in none of these did the fœtal tissues yield typhoid bacilli, whereas in the three cases when the examination was made during the fourth or a later week of the mother's illness the organism was present in the child each time. This number of patients is too small to generalise from but the results seem to indicate that before the end of the third week of the mother's illness the child is much less likely to have become infected than it is in the fourth or a later week. It seems probable that the prognosis as regards the immediate and subsequent life of the child will be much better if the infant could be born before this bacterial infection occurs. If therefore the pregnancy has reached the time when the child is viable, and if for any reason it is much desired that a living child should be born, it would seem that the best advice for the physician to give would be that of obtaining obstetric assistance for bringing about delivery before the mother's illness had reached the end of the third week. This advice would not be necessary if the mother's interests alone were to be considered, for in her case the prognosis is not materially affected by allowing the pregnancy to take its own course; but if the child's life is a material consideration it would appear to be very risky to allow it to remain in utero beyond three weeks from the beginning of the typhoid fever. With each week of the fever the chances that the child will become infected with typhoid bacilli rapidly increase.

Other Specific Fevers in the Unborn Child.

The discussion upon typhoid fever in conjunction with pregnancy has been somewhat dwelt upon, because, owing to the comparative ease with which both typhoid bacilli and agglutinins can be looked for, the cases afford an admirable field for investigation; they constitute natural experiments in man upon the trans-placental transmission of disease upon which there is scope for much more work in future cases. Much might be said about the other specific fevers also but there is only room for a few words about each here.[20]

Small-pox has long been known to be transmissible from the mother to the fœtus in utero. It by no means follows, of course, that the child has the eruption in every case in which the mother suffers from the disease during her pregnancy. Sometimes the fœtus has died before the exanthem could appear upon it. Sometimes the child will be born quite healthy and catch the complaint at birth—a post-natal, and not an antenatal, infection. Sometimes when the mother has had variola early in her pregnancy the latter has continued to term and the child, though exhibiting no external evidence of having had small-pox, has been noted to possess a natural immunity to the disease in after life. In quite a number of cases, however, the child has been born with the typical eruption of small-pox upon it. The degree to which the infant is affected is very variable, bearing no direct relationship, apparently, to the severity of the disease in the mother. The stage of the eruption in the child may be almost identical with that in the mother, varying from vesicle to scar according to the length of time the pregnancy has continued after the mother was taken ill. It is noteworthy that the eruption goes through a pustular stage in the unborn child just as it does in an adult; and, as a rule, the size of each lesion is greater than that seen in grown-up people. On the other hand, the duration of the eruption on the skin of the child may apparently be much longer than it is in adults, for in Laurens's case,[21] quoted by Dr. Ballantyne, the mother had small-pox early in her pregnancy, and two and a half months later the premature infant was born still covered with the eruption. Dr. Allan Warner[22] records an interesting case of the same kind. The mother was taken ill with small-pox upon Jan. 8th when four months pregnant. The eruption appeared upon her on Jan. 11th; by the 23rd the crusts were falling off, and by Feb. 3rd she was quite free from all scabs. Pregnancy continued until the 15th when miscarriage occurred; twin female children were delivered, both being well covered with a typical small-pox eruption in the pustular stage.

Another very remarkable fact is that the father may have small-pox at the time of conception, the mother may show no sign of the disease, and yet her child may have it in utero—a point which seems directly analogous with some cases of congenital syphilis. This opens up a wide field for discussion but one upon which it is not possible to enter here.

Three further points may be briefly noticed. First, there seems to be no stage of fœtal life, from the third month onwards, at which the child may not be born with the eruption upon it. Secondly, even if there is no eruption upon the child's skin it is very possible that owing to the route of infection being by the blood stream the lesions might be found upon mucous surfaces, a point which, as Dr. Ballantyne says, deserves full investigation in future cases. Thirdly, it might well be asked, What would be the behaviour of the child in regard to vaccination if the mother had been vaccinated successfully during the pregnancy? It seems clear[23] that two-thirds of such children are just like other children and "take" well at the usual time after birth, but that one-third prove insusceptible to vaccination for a short time after birth. The latter cases will, however, "take" six months or so later. It seems, therefore, that there may be a transmission of immune substances from the mother to the child in utero, but that even when this passive immunisation of the infant by maternal vaccination occurs it is quite transitory. It is therefore no argument against vaccination of the child that the mother has been vaccinated during the pregnancy, though it might be wise to counsel waiting for six months or a little longer before vaccination is performed in order to be more sure of its being successful at the first attempt.

Dr. Cordes has published an interesting case. The mother had small-pox during pregnancy and recovered. The child was born later and was vaccinated in the usual way but failed to "take." When it grew up vaccination was repeated on two further occasions, failing to "take" each time. Soon afterwards the young man went to China, caught small-pox, and died from it. It would seem here as though the mother's small-pox had rendered the child insusceptible to vaccination without at the same time rendering him secure from small-pox itself. Not only was he not secure from the disease but he took it with fatal severity. The importance of a possibility of this kind is obviously great.

Just as variola may be transmitted from mother to child in utero, so may other specific fevers. The total number of cases in which such a disease as measles coincides with pregnancy is naturally not great and the number of instances in which the child is born during the stage of the exanthem in the mother is still smaller. The total number of recorded cases of fœtal measles is therefore not great but Dr. Ballantyne[24] describes some and has collected altogether 20. *He also records cases of fœtal scarlet fever, chicken-pox*, mumps, pertussis, influenza, rheumatic fever, relapsing fever, yellow fever, cholera, malaria, and even cerebro-spinal fever and anthrax. There is clearly too little time at our disposal to give an account of all of these but after what has already been said in regard to the transmission of typhoid bacilli from the mother to the fœtus it may be of special interest to say a few words about the last two.

A most conclusive case of fœtal cerebro-spinal meningitis is recorded by Dr. Ballantyne. The mother died from the disease, the seven months child remaining in utero. At the necropsy there was the typical lesion in the maternal meninges, over both the brain and the spinal cord, whilst the meninges of the fœtus exhibited precisely similar changes, and the diplococcus intracellularis meningitidis was cultivated separately both from the mother and from the child.

In regard to anthrax, Rostowzew[25] investigated three cases in which the mothers died from the effects of malignant pustule and he found numbers of the anthrax bacilli in the placental intervillous spaces and in the fœtal villi, smaller numbers being also present in the fœtal blood and viscera.

There is abundant proof, therefore, that notwithstanding the "barrier action" that the healthy placenta may exert in protection of the child from injurious substances, the barrier may become broken down, or at least passed, as the result of many different diseased states in the mother; and that not only chemical substances in solution but also comparatively large concrete bodies such as bacteria may then gain access to the child. Before leaving this subject a few words may be said as to the effects of some of these fevers upon the mother.

THE EFFECTS OF MEASLES UPON THE PREGNANT WOMAN.

Pregnancy does not confer any immunity against the taking of measles. A pregnant woman who has not had the disease should therefore avoid exposure to infection. Should she develop the illness the prognosis as regards herself is good, but there is a considerable danger of abortion or premature delivery during the eruptive stage. It has been suggested[26] that measles affects the mucosa of the uterus as it does that of the nose, pharynx, eyes, stomach, bronchi, bladder, and bowel, causing an inflammatory congestion similar to that which has been observed in some cases of variola, and thereby accelerating miscarriage. If the exanthem stage is past there seems to be little or no danger either to the mother or to the child, unless the former should develop broncho-pneumonia, in which case, owing to the abdominal condition, *especially in the later months, the* dyspnœa and the repeated attacks of coughing may be a source of greater trouble and anxiety than usual.

THE EFFECTS OF PERTUSSIS UPON THE PREGNANT WOMAN.

The latter applies also to whooping-cough during pregnancy. Pertussis in an adult is very apt to be exceedingly distressing in any case, but when it is combined with pregnancy the patient may be in a very pitiable plight. The paroxysms of rapidly repeated cough, each bout sometimes terminating only in the ejection of some of the gastric contents, render the patient abjectly miserable. There is a danger of premature emptying of the uterus in consequence of the extreme and constantly repeated contractions of the diaphragm and abdominal muscles, but otherwise the prognosis is good both as regards the mother and the child.

THE EFFECTS OF SCARLET FEVER UPON THE PREGNANT WOMAN.

Scarlet fever arising in a pregnant woman has a relatively much graver prognosis than it has in other cases. The complication is least serious when it occurs early in the pregnancy and when it does not lead to abortion. It is, however, much rarer at this time than it is towards the end of pregnancy—so much so that it has been thought that the pregnant state confers some degree of immunity to it. The converse is true of the puerperium, when the patient is particularly liable to the infection, and whether the scarlet fever begins either immediately before or immediately after labour, *not only is the intensity of the disease itself*, its rash and its pyrexia, apt to be extreme, but also there is a very great liability to sapræmia, or, still worse, to actual septicæmia from streptococcal invasion. This view is not held by all; indeed, Dr. R. Boxall,[27] in a series of papers before the Obstetrical Society in 1888, contended that scarlet fever begets scarlet fever even in a pregnant woman, and has no relation to puerperal septicæmia. Dr. F. Foord Caiger, however, gives it as his opinion, from personal experience, that the conjunction of scarlet fever with present or recent pregnancy near to term cannot but be viewed with the gravest anxiety. The maternal mortality varies in different epidemics, but it may be as high as 75 per cent.

THE EFFECTS OF CHICKEN-POX AND MUMPS UPON THE PREGNANT WOMAN.

Chicken-pox is often much more severe an illness in adults than it seems to be in children, but there is no evidence to show that its occurrence in conjunction with pregnancy makes it any worse. The prognosis as regards both the mother and the child is good; though, as has been stated, the child may be born with the eruption upon it if the mother suffers late in the pregnancy.

The same remarks apply to mumps. It is, perhaps, a little surprising that mumps do not act very detrimentally upon the pregnancy, seeing that there is a considerable tendency for the parotitis to be associated with inflammation of the genital organs—ovaritis in woman, orchitis in man. The existence of pregnancy does not seem to render the patient more liable to ovaritis than usual, however, and the pregnancy often continues undisturbed.

THE EFFECTS OF DIPHTHERIA UPON THE PREGNANT WOMAN.

The pregnant state confers no immunity to infection by diphtheria and the disease appears to have a particular virulence in the case of pregnant women. There was a discussion upon the subject in THE LANCET[28] in 1903, and Dr. Chambrelent and Dr. Michelean[29] have collected together a number of cases in Bordeaux. The statistics available are open to the objection that they are based upon cases taken from the literature and not upon a consecutive series of unselected cases. Nevertheless two things seem clear: first, that the diphtheria is particularly prone to attack the larynx in these cases, as in children, rather than the fauces as in other adults; secondly, that if antitoxin is not employed the mortality is very great. Of Dr. Chambrelent and Dr. Michelean's cases there were 12 who received no antitoxin, and six of them died, a mortality of 50 per cent. All their cases in which serum was given recovered. Mr. A. E. Kennedy[30] points out that even the giving of antidiphtheritic serum early will not save every such case; nevertheless the proportion of recoveries is so much greater when serum is used early than when it is not that it should always be given at the earliest possible moment to a pregnant woman who has diphtheria.

THE EFFECTS OF SMALL-POX UPON THE PREGNANT WOMAN.

The effects of small-pox upon pregnancy have been closely observed in an epidemic during which there were opportunities of watching 432 consecutive cases in women under 50, 80 of whom were pregnant.[31] Of the latter, 15 per cent. died, whilst the mortality amongst the non-pregnant women was 11 per cent. The prognosis is, therefore, rather worse when the woman is pregnant, though not so much worse as might have been expected. The statistics are here, but I need not read them. In the 80 pregnant cases confluent small-pox was seen in four and hæmorrhagic in six; all ten died. In the 352 non-pregnant cases the confluent form was observed in three and the hæmorrhagic in 11; two of the confluent cases recovered. Two pregnant women died, though their small-pox was of the mild type. Of the primiparæ, 9 per cent. died; of the multiparæ, 17·25 per cent. The general impression during the epidemic was that there was a tendency for the pregnant women to suffer from a severer type of the disease than the others. The prognosis as regards the child is grave. Of the 80 cases, 23 aborted or had premature delivery; 16 other children were delivered alive in cases where the small-pox was in progress—eight at term and eight prematurely; only three out of the 16 children lived longer than six months. In two cases the small-pox eruption was present upon the child at birth.

CHOLERA AND PREGNANCY.

Cholera is fortunately of rare occurrence in European countries, but occasionally there are epidemics such as that at Hamburg. Schütz[32] published a complete report of the influence of cholera upon menstruation, pregnancy, labour, and child-bed in the annual report of the Hamburg State Infirmary at that time. He treated 2500 adult females during the epidemic, and found that cholera shows a marked tendency to affect the uterus. In the cramp stage of the disease uterine bleeding occurs in one-third of the non-pregnant cases. It is not surprising, therefore, that the effects of cholera upon pregnancy are disastrous. 115 of the patients were pregnant at the time they were taken ill with cholera; and Schütz puts this disease upon a level with small-pox in the way it is almost certain to provoke interruption of pregnancy. Kovalsky[33] finds the same to hold good in Russia, where over 80 per cent. of the pregnancies come to an untimely end in cholera patients. The prognosis as regards the mother, bad as it is in many of the cases, is not much worse in pregnant than it is in non-pregnant persons, particularly if the mother is taken ill when the pregnancy is not advanced. There is nothing to be gained by advising steps to be taken to terminate the pregnancy; indeed, convalescence is greatly impeded during the puerperium, and the risk of sepsis is greatly increased, so that the pregnancy should be allowed to continue if it will.

PLAGUE AND PREGNANCY.

The above remarks concerning cholera apply with equal force to plague. Pregnant women show no particular immunity to this disease. The prognosis as regards the mothers is no worse than it is in non-pregnant patients, but the disease terminates the pregnancy in the great majority of cases. Dr. B. H. F. Leumann[34] records some instances in which the mothers recovered exceedingly well, but there seem to be fewer statistics in regard to the effects of plague upon pregnant women than there are concerning cholera.

MALARIA AND PREGNANCY.

The effects of malaria upon pregnancy are necessarily variable, both on account of the varying severity of the malarial attacks in different patients and in different climes, and also because the immediate surroundings of the patient are so very diverse in different parts of the tropics. It is not easy, therefore, to summarise them in any but quite a broad way. There are papers by Italian observers[35] upon the subject and a few in English, notably one by Mr. F. H. Edmonds[36] of Demerara. The general conclusions which may be drawn are that malarial cachexia has almost no influence upon pregnancy and its course; that in mild cases of intermittent malaria pregnancy usually continues normally to term notwithstanding the ordinary attacks of fever in the mother; that in cases where the maternal temperature reaches 104° F. during the attacks abortion takes place in a large proportion of cases; whilst in the bilious remittent type of the disease not only is the pregnancy almost certain to terminate prematurely, but also the child, even if it has reached a viable age, is nearly always dead, and the prognosis as regards the mother is distinctly graver than it would be in a non-pregnant person with the same degree of malarial illness. There is a very great tendency for both the fœtal movements and the uterine contractions to become excessive during the acute malarial attack. It has sometimes been urged that quinine should not be given in such large doses, or even at all, to a pregnant woman with malaria on the theoretical ground that this drug itself increases uterine contractions and predisposes to abortion, but in practice it has been found by Mr. Edmonds and others that the greatest tendency to premature delivery is in the cases where no quinine is given, and it is emphatically urged by those who have had experience that quinine should be given all the more on account of the conjunction of pregnancy with the malaria. It actually makes the uterine contractions less than they are in cases in which no quinine is given, and by diminishing the pyrexia and lessening the frequency of the attacks not only is the prognosis as regards the mother's life greatly improved, but also the chances that the child will be stillborn are very considerably diminished. It may be incidentally remarked that the infant is sometimes born with a greatly enlarged spleen, though there is not yet any absolute proof that the child's blood may actually contain the plasmodium malariæ at the time of birth.

INFLUENZA AND PREGNANCY.

Influenza is a disease the severity of which is so variable in different seasons that its effects upon pregnant women in particular are difficult to gauge. The statistics show that the prognosis is much graver in times of widespread epidemic than it is in sporadic cases, but this applies equally to non-pregnant as to pregnant patients. Jacquennier,[37] as long ago as 1837, came to the conclusion that influenza was no more dangerous to pregnant women than to anybody else. The type of the disease was different in those days, however, from what it is now, and Cazeaux regards it as likely to be detrimental to the child. The weakness that is left after the acute phase is past is apt to last even longer in the pregnant woman than it is in other persons, and therefore even if the pregnancy does not come to an untimely ending the child is very apt to be born with deficient vitality and a tendency to die young. Lambinon[35] regards the bronchitic or pneumonic form of influenza as the most grave as regards both the mother and the child; but all observers agree that nothing is to be gained by interfering with the pregnancy, and the treatment should be, first, prophylactic in times of epidemic; and, secondly, that of extremely careful medical supervision should the disease be contracted in spite of all precautions taken to avoid it.

During an epidemic of influenza in Paris M. Bar and M. Boullé[39] carefully watched the effects of the disease in 40 pregnant women. One of these had the nervous, two the gastro-intestinal, and 37 the respiratory form of the disease. Four of the latter developed influenzal pneumonia, two recovering slowly after delivery, one dying a few hours, and one on the third day after the child was born. The prognosis as regards the mother is, therefore, grave in the pneumonic type of influenza, but as regards the course of the pregnancy itself these observers came to the conclusion that it was not affected even if the influenza was severe.

LOBAR PNEUMONIA DURING PREGNANCY.

As regards ordinary lobar pneumonia in a pregnant woman, exclusive of pneumonia developing during the puerperium, the cases that have been in Guy's Hospital point to the following conclusions. 1. *If the pneumonia occurs early in the pregnancy*, the prognosis as regards the mother is little if any worse than it is in other patients of the same age. As regards the pregnancy there is a probability that abortion will take place in about one-third of the cases, whilst in two-thirds of the cases there is a likelihood not only that the mother will recover completely but also that the child will be born living and healthy at term. 2. *If, on the other hand, the pneumonia develops during the second half of pregnancy* the probability is that the latter will be then terminated in two-thirds of the cases and the chances of the mother surviving will be greatly diminished, nearly half the patients dying if the pneumonia sets in after the sixth month. In other words, the more advanced the pregnancy the greater is the probability of an expulsion of the fœtus and the graver the prognosis for the mother. Dr. Hirst[40] found that out of 43 cases of lobar pneumonia in pregnant women 28 were less than six months pregnant and of these 11 aborted; of the 15 who were more than six months pregnant ten aborted, and of these 15 mothers seven died.

The question might be asked: Seeing that the prognosis as regards the child is in any case grave, might it not be wise to counsel termination of the pregnancy for the mother's sake if pneumonia sets in? The answer is definitely, No. Matton[41] records that out of 38 cases of pneumonia during pregnancy labour was induced in 18, and nine of these patients died—a mortality of 50 per cent.; whereas of the 20 cases left to themselves only one died. These figures are not very new, and in interpreting them it must be remembered that labour would probably be induced chiefly in the worst cases, so that the high mortality cannot be entirely attributed to the treatment; but it is clear that the chances of the patient's recovery are at any rate not increased by interfering with the pregnancy, so that the right course to pursue is to treat the patients exactly as if they were not pregnant, unless nature itself makes obstetric assistance necessary.[42]

It is wonderful how much illness a patient, even though she be pregnant, can pass through and yet recover from. Dr. Francis Hawkins,[43] for instance, records a case of a lady, aged 35 years, who, when four months pregnant, developed double basic pneumonia, followed by endocarditis, severe bronchitis, acute dilatation of the heart, and finally by empyema. The pregnancy continued up to the sixth week after the onset of the illness, and had it not been for the empyema it would apparently have continued to term. The empyema was treated in the usual way, by rib resection, and ultimately, after a long illness of extreme severity, the patient got perfectly well.

Another case[44] illustrates the possibility of good results in spite of a grave prognosis. The patient was 38 years of age, and when eight and a half months pregnant she was seized with lobar pneumonia in the left lung. She was extremely ill. The crisis came on the seventh day, but very shortly afterwards she was as dyspnœic as ever and the temperature rose again. A week after the crisis pus was located in the left pleural cavity and 34 ounces of it were drawn off by aspiration. It was hoped that rib resection might be avoided, but three days later it was necessary to give chloroform and drain the empyema. The patient was now at full term and a few hours after the operation a strong healthy child was born, labour being easy and convalescence uneventful.

The pneumococcus may cause other lesions than pneumonia in a pregnant woman, but there is little evidence to show that the association is not due to chance. Vinay,[45] for example, records the case of a woman who, having suffered from great gastric irritability throughout her pregnancy, developed multiple subcutaneous abscesses during the seventh month. The pus gave cultures of pneumococci. The patient made a long struggle but ultimately died 19 days after delivery. There was nothing in this case to show that the pregnancy was in any way directly concerned as a causal factor in the pneumococcal infection.

ADDISON'S DISEASE AND PREGNANCY.

We may now pass on to quite a different class of illnesses in the mother.

Addison's disease in conjunction with pregnancy is necessarily rare. There seem to have been only two cases of the kind in Guy's Hospital in the last 20 years, and both patients died. It is always very difficult to give an accurate prognosis in any case of Addison's disease, patients often dying almost suddenly when there has been no objective alteration in their general state for months previously. Consequently it is not possible to say that it was the pregnancy that hastened the end in these two cases. Nevertheless, the impression left upon one's mind is that the added strain of pregnancy was the immediate cause of death and that pregnancy is therefore a very bad thing for a patient who has Addison's disease.

There is another point to mention, and that is the possible difficulty in diagnosis. Pregnancy itself may cause considerable increase in the pigment of the patient's skin, and the symptoms of weakness, vomiting, and even syncope may be attributed to the pregnancy itself in a case in which the pigmentation is not extreme and in which the buccal mucosa has not been examined in a good light.

The two cases mentioned above were so similar to one another in most respects that the following notes of one of them may be taken to apply to both. The patient was 40 years of age, had had 11 children, the last two and a half years previously, and she was now five and a half months pregnant. She had begun to suffer from weakness, syncopal attacks, and undue pigmentation of the skin and buccal mucosa six months before she became pregnant, and Addison's disease had been diagnosed. At first the symptoms were not greatly increased by the pregnancy, but from the fourth month onwards the patient became distinctly weaker; attacks either of vomiting or syncope became so frequent that obstetric measures for terminating the pregnancy were adopted in the middle of the sixth month. The pulse-rate rose rapidly after delivery and the heart's action became very feeble. There were several ill-defined convulsive seizures and death occurred two days after labour. It may be mentioned that treatment by adrenalin had been pursued. At the necropsy both suprarenal capsules were typically caseous and there was no other macroscopic disease.

LEUKÆMIA AND PREGNANCY.

Turning now to leukæmia, the cases may be divided into the acute and the chronic; and these are almost synonymous with the lymphatic and the spleno-medullary varieties. The acute form ends so rapidly in any case—usually within a few months of its first symptoms—that pregnancy is not at all likely to arise in a person who already has the disease. Acute leukæmia may, however, develop in a woman who is pregnant and the summary of what then happens is: that, bad though the prognosis is in other cases, the conjunction of pregnancy with the disease makes it still worse. Whether the association is accidental or whether something anomalous about the pregnancy may perhaps cause the leukæmia, it is hardly possible to say; but judging from the rarity with which the two are associated their conjunction would seem to be accidental. Hilbert[46] records the case of a woman, aged 37 years, who had been perfectly well up to the eighth month of her eighth pregnancy. She then complained of severe headaches, diarrhœa, fever, and gingivitis. Rhinitis and purpura followed; and blood examinations indicated typical lymphatic leukæmia. The pregnancy continued to the ninth month, when a macerated child was born spontaneously. The mother died from complete exhaustion ten hours after the labour and a little more than a month from the onset of her symptoms.

Spleno-medullary leukæmia, on the other hand, may last for three or four years after the first symptoms lead to its diagnosis and pregnancy may arise in a patient who is already known to have the disease. Dr. Herman[47] has recorded one such case and has collected altogether seven undoubted others. Owing to the enlarged spleen pregnancy gave much more abdominal distension than normal; in some cases, indeed, it is wonderful how both the huge spleen and a full-term pregnancy can be included in the same abdomen. It is not surprising that there is a great tendency to premature delivery. The puerperium is a very dangerous time, some of the patients dying very soon after the termination of the pregnancy, though if the patient survives the particularly dangerous time that immediately follows delivery considerable temporary improvement in her general health is to be expected. Dr. Herman concludes that pregnancy does nothing but harm to a leukæmic patient and recommends that it should be artificially terminated as soon as possible.

It would be very interesting to know whether the children of leukæmic patients are ever born with enlarged spleens similar to the enlargement of that organ sometimes found in the offspring of parents suffering from malaria.[48] It would also be interesting to know what effects upon the pregnancy repeated applications of the x rays to the maternal abdomen would have. There are no statistics upon the subject. Evidence is accumulating to show that x ray applications may be very efficient in diminishing the size of the spleen and in ameliorating the symptoms for the time being in cases of spleno-medullary leukæmia. If it were known that their application to the splenic region in the mother had no ill-effect upon the child, it might be well to advise leaving the pregnancy to run its course whilst the leukæmia was simultaneously being treated with the x rays. In the absence of evidence either way, however, it would seem likely that the x rays would do harm to the child, in which case rather than risk the mother's life unnecessarily, the right course to advise would seem to be to have the pregnancy terminated as soon as possible and then to adopt the x ray treatment if it still seemed good to do so.

DIABETES MELLITUS AND PREGNANCY.

Diabetes mellitus in conjunction with pregnancy has many points of interest. There has been much discussion as to the nature of the reducing bodies that are often present in the urines of pregnant women, especially in the later months. There is no doubt that lactose is commonly present, both towards the end of pregnancy and during the puerperium; but it seems equally clear that a considerable proportion of pregnant women have actual glycosuria.

Saleim,[49] as the result of careful examinations, states that two-thirds of all pregnant women pass increased quantities of glucose in this way. This glycosuria of pregnancy causes no symptoms, however, and it disappears without treatment. It seems therefore to bear no relationship to diabetes mellitus itself. Nevertheless, seeing that pregnancy thus predisposes to glycosuria and seeing that, if they can become pregnant, the patients who are suffering from this complaint must necessarily be comparatively young and therefore predisposed to the worst form of diabetes mellitus, it might well have been expected that pregnancy would be very harmful if it occurred in a patient already suffering from diabetes mellitus. It is difficult amongst hospital cases to be sure that the glycosuria has ante-dated pregnancy, and only two clear instances of the kind have occurred in Guy's Hospital lately. One of these patients was a very stout woman, aged 36 years, whose pregnancy went naturally to term although her urine was loaded with sugar and also contained both diacetic acid and acetone in abundance. The other was a younger woman, aged 23 years, whose urine also contained sugar, diacetic acid, and acetone, and whose pregnancy ran a perfectly normal course, ending in the birth of a healthy child at term. In both these cases there was a large excess of liquor amnii; this has been noticed by several observers as being almost characteristic in the case of diabetic mothers and the amniotic fluid often contains sugar.

It is not every case that passes through pregnancy with as little trouble as the above. Ludwig,[50] for example, records a severe case in which a woman, aged 42 years, was in her ninth pregnancy. Marked diabetes mellitus had existed for two and a half years, but she had reached the last month of this pregnancy without any trouble beyond pruritus vulvæ. The abdomen now became suddenly larger and the patient was admitted to hospital very ill, semi-conscious, with abundance of sugar, diacetic acid, and acetone in her urine. Labour was induced, nine pints of liquor amnii escaping. The fœtus was in an advanced state of maceration. The patient was very ill for two days afterwards, but she slowly recovered, though her diabetes persisted as before. It is interesting to note that the hydramnios occurred suddenly in this case; and it is also noteworthy that the fœtus was macerated, for it may have been on this account that the mother was so ill.

The general conclusions that other recorded cases[51] point to are: that diabetes mellitus is by no means incompatible with pregnancy; that cases of moderate severity are not made materially worse by pregnancy; and that there seldom seems to be any reason for interfering with the pregnancy.

Some observers[52] have even stated their opinion that pregnancy, instead of making the diabetes worse, actually ameliorates it for the time being—a point of great interest when one recalls the effects of typhoid fever, for example, in similar cases. A patient with diabetes mellitus may develop typhoid fever, and during that illness the glycosuria may entirely cease, returning again when the fever subsides.

DIABETES INSIPIDUS AND PREGNANCY.

Diabetes insipidus is a condition which may actually arise during pregnancy as the result of a severe mental shock at that time. Should it do so, it seems that it does not go away again after the child is born. It may also have existed previously to pregnancy. The chief trouble to the patient is the fact that when the uterus enlarges there is less room for the bladder; micturition becomes annoyingly frequent and acute retention of urine is apt to occur if micturition is postponed. Sleep may become very broken in consequence of this and also because of the constant necessity for drinking water or other liquid. The pregnancy itself runs no abnormal course, the children may be perfectly healthy, and there is no marked tendency to hydramnios with its inordinate abdominal distension such as occurs in diabetes mellitus.

There seems to have been no case of extreme diabetes insipidus in association with pregnancy in Guy's Hospital, but in one medium case the patient, a very stout woman, was passing up to 15 pints of limpid urine daily, of specific gravity 1003. The water alone was increased, the total solids being normal. In this instance the polyuria and polydipsia had not been present until the middle of the fifth pregnancy, when these symptoms came on suddenly after a severe fright. If the patient failed to micturate directly the desire came she developed retention of urine, necessitating the use of a catheter, and on some such occasions the bladder contained as much as four pints at a time. The child was born normally but the polyuria and polydipsia persisted.

Cases of diabetes insipidus in association with pregnancy have been recorded by Bennett, Matthews Duncan, Esterle, Merbach, Kleinwachter, Vinay,[53] and others. The two following may be mentioned in particular because they are instances of diabetes insipidus developing from mental shock and because they show that although the diabetes insipidus does not seem to be in itself dangerous the patients are apparently more liable than others to contract, and die from, intercurrent maladies of the lungs.

One patient was a woman, aged 32 years, who kept a farm. When she was pregnant a flood destroyed all her crops and immediately after this severe mental shock polydipsia and typical diabetes insipidus set in. The patient passed up to 5¼ gallons of urine daily yet became pregnant for the second time. During the pregnancy the polyuria abated somewhat, the least quantity of urine passed in one day being nine pints. Delivery was normal; thereafter the urine at once increased in quantity again but the patient left the hospital otherwise in good health. Shortly afterwards, however, she died from double pneumonia.

The second patient was a woman, aged 26 years, who was four months pregnant for the fifth time when a fire destroyed her house and all she possessed. Diabetes insipidus set in directly, 20 pints of almost pure water passing daily; the total solid constituents of the urine were normal. Labour occurred normally at term but the

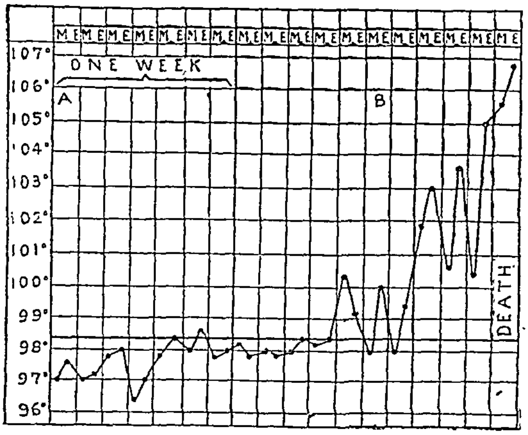
child was sickly and died in two weeks. The patient continued to have polyuria; she developed phthisis and died 19 months after the fire.

MYXŒDEMA AND PREGNANCY.

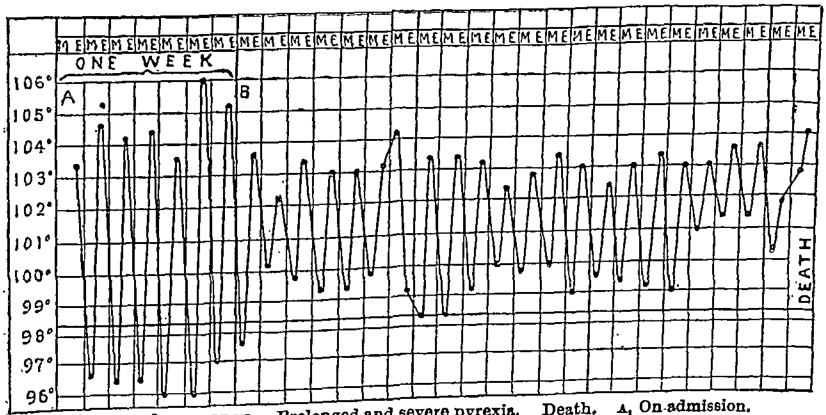
There do not seem to be many recorded cases of pregnancy in patients suffering from myxœdema. Apparently this disease is not incompatible with conception, at any rate in persons who are receiving thyroid treatment; in the one case observed by me the pregnancy had no ill-effect upon the mother's condition, and if it had not been for the accident that her pelvis was much contracted there seems to be no reason why she should not have borne children naturally. As regards the child, the main danger is that it will have a deficient thyroid gland and be a cretin, unless upon the first suspicion of this treatment with some preparation of thyroid gland is begun. The patient in question was 40 years of age and enormously stout. She had been receiving thyroid treatment for her myxœdema for over two years. Her pregnancy went to full term and natural labour came on, but there were great obstetrical difficulties which need not be recounted. The recuperative power of the patient, notwithstanding her myxœdema, is evidenced by the fact that she ultimately got quite well in spite of long-continued sapræmia and a "white" arm due to thrombosis of the right axillary vein.

CHART 4.



Chorea and pregnancy. Pyrexia. Death. A, On admission. B, Accouchement forcé.

CHART 5.



Chorea and pregnancy. Prolonged and severe pyrexia. Death. A, On admission. B, Spontaneous premature delivery.

There is no time left for the discussion of a number of other conditions that one would like to enter upon, such as the effects of pregnancy upon Graves's disease, upon ordinary goitre, upon malignant disease, upon phthisis, upon heart disease, upon chorea, and upon many other things which are full of interest. The varieties of jaundice that may occur during pregnancy might form a chapter by themselves. There is a whole group of cases in which a pregnant woman dies and nothing very abnormal is found at the post-mortem examination to account for her death. It is with regret that one is obliged to leave out these for want of time. My views have already been expressed about some of them elsewhere,[54] however; and if I may be pardoned for making one more remark it is in connexion with chorea gravidarum.

CHOREA AND PREGNANCY.

Mr. H. T. Hicks and myself[55] have expressed the view that "'simple' chorea gravidarum is to fatal chorea gravidarum as 'simple' endocarditis is to fungating endocarditis," and that the violence of the choreic movements is not of nearly so great importance in estimating the prognosis as is the presence or absence of pyrexia. Out of 29 consecutive cases of the disease at Guy's Hospital 26 patients recovered and three died. In none of the 26 cases of recovery was there any material pyrexia, although in some of the cases the movements were very violent; in the cases that died, on the other hand, there was marked pyrexia in every instance. There will doubtless be exceptions, but as a broad rule we suggest that, provided the temperature remains almost normal, as in Chart 3, the prognosis is good even if the movements are very violent, whereas if the chart shows marked pyrexia, uninfluenced by salicylates, as in Charts 4 and 5, the prognosis is very grave, provided no obvious cause, such as pleurisy, acute tonsillitis, and the like, can be found to account for the fever. It will be very interesting to see whether other observers will find this to hold good in future cases that may come under their notice.

I thank you, Mr. President and Gentlemen, for listening so patiently to these lectures, and I will conclude by reverently recalling to your thoughts the name of their founder, Dr. Goulston.

These lectures are open without fee to all students of the London medical schools, as well as to registered practitioners, on presentation of their cards.

JUVENILE TABES DORSALIS: NOTES OF FIVE CASES.

BY SYDNEY STEPHENSON, M.B., C.M. EDIN., F.R.C.S. EDIN.,

OPHTHALMIC SURGEON TO THE EVELINA HOSPITAL, THE QUEEN'S HOSPITAL FOR CHILDREN, HACKNEY ROAD, LONDON, ETC.

A REMARKABLE communication on juvenile tabes dorsalis by Dr. A. Cantonnet, of the Hôtel Dieu, Paris,[1] has once again brought this rare and interesting disease to the front. Dr. Cantonnet, after describing a case of his own in a lad aged 15 years, analysed 89 cases of juvenile tabes dorsalis which he had collected from the literature, and reached some important conclusions with regard to the malady. For example, in 57·1 per cent. of the cases there was certain evidence of inherited, and in 8·5 per cent. of syphilis acquired during the first years of life; total, 65·6 per cent. Moreover, in 13·90 per cent. of the cases personal stigmata were found in choroido-retinitis or in interstitial keratitis. The part played by syphilis in the production of the malady, therefore, is as considerable as in adult tabes dorsalis. Direct heredity was not common. In 15·30 per cent. of the cases analysed by Cantonnet one of the parents was tabetic, and in 12 per cent. one was affected with general paralysis. Juvenile tabes dorsalis, which, on the average, commences at 15 years of age, affects females in 62·6 per cent. as against males in 37·3 per cent., a striking and as yet unexplained contrast to the sex-incidence in later life, which is given by Gowers[2] as "about ten to one." The ocular symptoms of juvenile tabes dorsalis include inequality of the pupils, the Argyll Robertson phenomenon (simple or complicated), optic atrophy, paralysis of the extrinsic muscles of the eye, latent ocular ataxy, and so forth. According to Cantonnet the prognosis as regards sight in juvenile tabes dorsalis is unfavourable, seeing how common optic atrophy is. On the other hand, as regards life, it is relatively good, since among 12 patients whose history was followed for from 10 to 20 years after the beginning of the affection there was not a single death. It must not be forgotten, however, that (as in the adult) general paralysis may supervene, and, indeed, four such instances are included among the cases collected by Cantonnet.

That juvenile tabes dorsalis, like adult tabes dorsalis, may assume various clinical guises is well known. Thus, there is a group of cases mainly characterised by "lightning pains" in the legs or the arms, ataxy of the limbs, and loss or reduction of the knee- and ankle-jerks. It is to be noted that in about one-quarter of Cantonnet's cases (25·2 per cent.) the disease commenced with "lightning pains." In another group, which it is the more particular object of this brief communication to describe, the prominent symptoms include amblyopia due to optic atrophy, together with changes in the pupillary reflexes, and abolition of the knee- and ankle-jerks. Amblyopia was the first sign noted in 14 per cent. of Cantonnet's series, and in no fewer than 43·9 per cent. optic atrophy, complete or incomplete, was present. Ataxy is often conspicuous by its absence in this class of case, thereby bearing out what is sometimes known as "Benedikt's law," which is to the effect that ataxic symptoms disappear or fail to develop on the advent of optic atrophy. Cantonnet's figures with regard to this point are as follows: among 40 cases of optic atrophy there were 70·5 per cent. without ataxy, 20 per cent. with slight ataxy, and 9·5 per cent. with pronounced ataxy. This variety of juvenile tabes dorsalis appears to correspond with those familiar to every ophthalmic surgeon in adults under the name of "pre-ataxic optic atrophy." It is the class that is very likely to fall, in the first instance at any rate, under the notice of the ophthalmologist rather than of the general physician. It is important that we should be familiar with the diagnosis of such cases, if only for the purpose of getting the patients under suitable medical treatment without loss of time.

Confusion may arise between juvenile tabes dorsalis, on the one hand, and Friedreich's ataxy, on the other. In well-marked cases, however, the distinction is not difficult. The salient characteristics of Friedreich's ataxy are (1) nystagmus and (2) associated deformities, such as pes cavus and lateral curvature of the spinal column. The "lightning pains," the pupillary signs, and especially the optic atrophy of tabes dorsalis, are absent from the other affection. The bilateral atrophy of the optic discs coming on in young subjects might lead to some confusion with that peculiar abiotrophy known as "hereditary optic atrophy," which is liable to attack more than one member of a family at or about puberty. "Leber's disease," as it is sometimes called, is, however, usually preceded by optic papillitis, and even when the appearances of optic atrophy are present yet the peripheral parts of the visual field retain their functions. The defect of vision, in other words, is in the nature of a central scotoma. In my opinion, it admits of little doubt that a proportion (perhaps a large one) of those cases in children where the sole obvious findings include amblyopia and optic atrophy are in reality instances of juvenile tabes dorsalis. I cannot doubt that a more systematic investigation of the nervous system than is usually feasible in an ophthalmic out-patient room would result in a more definite diagnosis of these cases. As matters stand, however, the association in a syphilitic child of bilateral simple optic atrophy with loss of the knee-jerks, would by itself point to a provisional diagnosis of juvenile tabes dorsalis, and suggest the need for systematic investigation by a neurological physician. Another suggestive combination would be paralysis of an ocular muscle with loss of the deep reflexes in a syphilitic subject.

257

Cases of Juvenile Tabes Dorsalis.

CASE 1.—The patient, a boy, aged 13 years, came under my notice for the first time at the Evelina Hospital for Sick Children, London, on August 11th, 1899. His left eye was stated to have been blind and to have squinted outwards since the occurrence of a "fit" when he was a baby. On admission the right pupil was two millimetres and the left pupil five millimetres in transverse diameter. Neither pupil responded to light or to accommodation. The movements of the eyes were intact. R.V. = $\frac{6}{18}$ and No. 6 Jaeger; punctum proximum, 15 centimetres. L.V. = 1 no perception of light. There was incomplete optic atrophy, which was more pronounced in the left eye. The ophthalmoscopic appearances were those of so-called "simple" atrophy. The lad's face rather suggested syphilis. A small epithelial denudation lay beneath the right angle of the mouth. There were no fine deep vessels in the corneæ, such as might indicate a former attack of interstitial keratitis. But there was somewhat coarse pigmentation, together with other changes, over the lower half of the left fundus oculi, and also some choroidal disturbance about the outer side of the left optic disc. For more complete examination the patient was referred to my colleague, Dr. George Carpenter, who was kind enough to furnish me with the following report: "The only suspicious thing I can find about him is the fact that the fronts of his shins, upper third, are thicker than natural. The sharp line of the tibia is rounded, as also the anterior surface of the bone, both sides, suggests nodes." Jan. 31st, 1902: R.V. = $\frac{6}{6}$ and No. 1 Jaeger. L.V. = fingers at half a metre. The right pupil was very small (1 to 1·5 millimetres); there was no response to light but there was slight action to accommodation. The left pupil, which measured five millimetres, was devoid of action either to light or to accommodation. Right field of vision for white full—90°, 60°, 65°, and 60° in the chief four meridians. The gait was not ataxic. Romberg's sign was absent. There was no rectal or urinary trouble. The boy gave an account of having suffered intense periodical pain in the left thigh and leg at times since I last saw him. It had been much worse than usual in May, 1901, but had been better since June of that year. The knee-jerks were absent; there was no ankle clonus.

In the foregoing case the diagnosis of juvenile tabes dorsalis was come to on the following grounds: (1) the syphilitic inheritance, as attested by the facies and the osseous and choroidal changes; (2) the absence of the knee-jerks; (3) the inequality of the pupils and the Argyll Robertson phenomenon; (4) the "lightning pains"; and (5) the bilateral optic atrophy.

It is of some little importance to notice that on the first visit (August 11th, 1899) the lad presented paresis of accommodation as regards his right eye, since his range of accommodation was only equal to a convex lens of 6 6 D., whereas it should have equalled at his age a lens of at least 12 D. spherical. When examined some two and a half years later this symptom had disappeared. Upon the whole, then, the case may be characterised as a fairly typical example of juvenile tabes dorsalis.

JUVENILE TABES DORSALIS: NOTES OF FIVE CASES.

BY SYDNEY STEPHENSON, M.B., C.M. EDIN., F.R.C.S. EDIN.,
OPHTHALMIC SURGEON TO THE EVELINA HOSPITAL, THE QUEEN'S HOSPITAL FOR CHILDREN, HACKNEY ROAD, LONDON, ETC.

A REMARKABLE communication on juvenile tabes dorsalis by Dr. A. Cantonnet, of the Hôtel Dieu, Paris,[1] has once again brought this rare and interesting disease to the front. Dr. Cantonnet, after describing a case of his own in a lad aged 15 years, analysed 89 cases of juvenile tabes dorsalis which he had collected from the literature, and reached some important conclusions with regard to the malady. For example, in 57·1 per cent. of the cases there was certain evidence of inherited, and in 8·5 per cent. of syphilis acquired during the first years of life; total, 65·6 per cent. Moreover, in 13·90 per cent. of the cases personal stigmata were found in choroido-retinitis or in interstitial keratitis. The part played by syphilis in the production of the malady, therefore, is as considerable as in adult tabes dorsalis. Direct heredity was not common. In 15·30 per cent. of the cases analysed by Cantonnet one of the parents was tabetic, and in 12 per cent. one was affected with general paralysis. Juvenile tabes dorsalis, which, on the average, commences at 15 years of age, affects females in 62·6 per cent. as against males in 37·3 per cent., a striking and as yet unexplained contrast to the sex-incidence in later life, which is given by Gowers[2] as "about ten to one." The ocular symptoms of juvenile tabes dorsalis include inequality of the pupils, the Argyll Robertson phenomenon (simple or complicated), optic atrophy, paralysis of the extrinsic muscles of the eye, latent ocular ataxy, and so forth. According to Cantonnet the prognosis as regards sight in juvenile tabes dorsalis is unfavourable, seeing how common optic atrophy is. On the other hand, as regards life, it is relatively good, since among 12 patients whose history was followed for from 10 to 20 years after the beginning of the affection there was not a single death. It must not be forgotten, however, that (as in the adult) general paralysis may supervene, and, indeed, four such instances are included among the cases collected by Cantonnet.

That juvenile tabes dorsalis, like adult tabes dorsalis, may assume various clinical guises is well known. Thus, there is a group of cases mainly characterised by "lightning pains" in the legs or the arms, ataxy of the limbs, and loss or reduction of the knee- and ankle-jerks. It is to be noted that in about one-quarter of Cantonnet's cases (25·2 per cent.) the disease commenced with "lightning pains." In another group, which it is the more particular object of this brief communication to describe, the prominent symptoms include amblyopia due to optic atrophy, together with changes in the pupillary reflexes, and abolition of the knee- and ankle-jerks. Amblyopia was the first sign noted in 14 per cent. of Cantonnet's series, and in no fewer than 43·9 per cent. optic atrophy, complete or incomplete, was present. Ataxy is often conspicuous by its absence in this class of case, thereby bearing out what is sometimes known as "Benedikt's law," which is to the effect that ataxic symptoms disappear or fail to develop on the advent of optic atrophy. Cantonnet's figures with regard to this point are as follows: among 40 cases of optic atrophy there were 70·5 per cent. without ataxy, 20 per cent. with slight ataxy, and 9·5 per cent. with pronounced ataxy. This variety of juvenile tabes dorsalis appears to correspond with those familiar to every ophthalmic surgeon in adults under the name of "pre-ataxic optic atrophy." It is the class that is very likely to fall, in the first instance at any rate, under the notice of the ophthalmologist rather than of the general physician. It is important that we should be familiar with the diagnosis of such cases, if only for the purpose of getting the patients under suitable medical treatment without loss of time.

Confusion may arise between juvenile tabes dorsalis, on the one hand, and Friedreich's ataxy, on the other. In well-marked cases, however, the distinction is not difficult. The salient characteristics of Friedreich's ataxy are (1) nystagmus and (2) associated deformities, such as pes cavus and lateral curvature of the spinal column. The "lightning pains," the pupillary signs, and especially the optic atrophy of tabes dorsalis, are absent from the other affection. The bilateral atrophy of the optic discs coming on in young subjects might lead to some confusion with that peculiar abiotrophy known as "hereditary optic atrophy," which is liable to attack more than one member of a family at or about puberty. "Leber's disease," as it is sometimes called, is, however, usually preceded by optic papillitis, and even when the appearances of optic atrophy are present yet the peripheral parts of the visual field retain their functions. The defect of vision, in other words, is in the nature of a central scotoma. In my opinion, it admits of little doubt that a proportion (perhaps a large one) of those cases in children where the sole obvious findings include amblyopia and optic atrophy are in reality instances of juvenile tabes dorsalis. I cannot doubt that a more systematic investigation of the nervous system than is usually feasible in an ophthalmic out-patient room would result in a more definite diagnosis of these cases. As matters stand, however, the association in a syphilitic child of bilateral simple optic atrophy with loss of the knee-jerks, would by itself point to a provisional diagnosis of juvenile tabes dorsalis, and suggest the need for systematic investigation by a neurological physician. Another suggestive combination would be paralysis of an ocular muscle with loss of the deep reflexes in a syphilitic subject.

257

Cases of Juvenile Tabes Dorsalis.

CASE 1.—The patient, a boy, aged 13 years, came under my notice for the first time at the Evelina Hospital for Sick Children, London, on August 11th, 1899. His left eye was stated to have been blind and to have squinted outwards since the occurrence of a "fit" when he was a baby. On admission the right pupil was two millimetres and the left pupil five millimetres in transverse diameter. Neither pupil responded to light or to accommodation. The movements of the eyes were intact. R.V. = $\frac{6}{18}$ and No. 6 Jaeger; punctum proximum, 15 centimetres. L.V. = ? no perception of light. There was incomplete optic atrophy, which was more pronounced in the left eye. The ophthalmoscopic appearances were those of so-called "simple" atrophy. The lad's face rather suggested syphilis. A small epithelial denudation lay beneath the right angle of the mouth. There were no fine deep vessels in the corneæ, such as might indicate a former attack of interstitial keratitis. But there was somewhat coarse pigmentation, together with other changes, over the lower half of the left fundus oculi, and also some choroidal disturbance about the outer side of the left optic disc. For more complete examination the patient was referred to my colleague, Dr. George Carpenter, who was kind enough to furnish me with the following report: "The only suspicious thing I can find about him is the fact that the fronts of his shins, upper third, are thicker than natural. The sharp line of the tibia is rounded, as also the anterior surface of the bone, both sides, suggests nodes." Jan. 31st, 1902: R.V. = $\frac{6}{5}$ and No. 1 Jaeger. L.V. = fingers at half a metre. The right pupil was very small (1 to 1·5 millimetres); there was no response to light but there was slight action to accommodation. The left pupil, which measured five millimetres, was devoid of action either to light or to accommodation. Right field of vision for white full—90°, 60°, 65°, and 60° in the chief four meridians. The gait was not ataxic. Romberg's sign was absent. There was no rectal or urinary trouble. The boy gave an account of having suffered intense periodical pain in the left thigh and leg at times since I last saw him. It had been much worse than usual in May, 1901, but had been better since June of that year. The knee-jerks were absent; there was no ankle clonus.

In the foregoing case the diagnosis of juvenile tabes dorsalis was come to on the following grounds: (1) the syphilitic inheritance, as attested by the facies and the osseous and choroidal changes; (2) the absence of the knee-jerks; (3) the inequality of the pupils and the Argyll Robertson phenomenon; (4) the "lightning pains"; and (5) the bilateral optic atrophy.

It is of some little importance to notice that on the first visit (August 11th, 1899) the lad presented paresis of accommodation as regards his right eye, since his range of accommodation was only equal to a convex lens of 6 6 D., whereas it should have equalled at his age a lens of at least 12 D. spherical. When examined some two and a half years later this symptom had disappeared. Upon the whole, then, the case may be characterised as a fairly typical example of juvenile tabes dorsalis.

---

[2] A Manual of Diseases of the Nervous System, vol. i., 1892, p. 399.

CASE 2.—The patient, a female, aged 24 years, attended the Royal Eye Hospital, Southwark, under the care of Mr. Robert W. Doyne, on Dec. 2nd, 1904, complaining that the sight of the left eye had been failing for about one year. On admission she was found to be a healthy but somewhat stupid-looking young woman, whose facies suggested hereditary syphilis. Her jaws were ill-developed and the upper central incisor teeth, although not typical, conveyed a strong suspicion of hereditary syphilis. The patient had recently *become somewhat deaf. Knee-jerks were absent, even on* reinforcement. Romberg's sign was not present. There was no trouble as regards the bowels, but recently the patient had been compelled to urinate more frequently and to do so the moment the desire seized her. The right pupil reacted feebly to light; the left pupil was motionless. Both pupils responded to accommodation. Reflex iridoplegia (Argyll Robertson phenomenon) was therefore present. Both optic discs, especially the left one, were pale and without ophthalmoscopic evidences of antecedent neuritis. The retinal vessels were of good size. There was no peripheral choroiditis; no fine vessels could be found in the corneæ; and no ectropion uveæ was present. R.V. = $\frac{6}{9}$. L.V. = shadows only. The patient, an orphan, was the eldest of three sisters, one of whom, aged 21 years, was examined by me on Sept. 18th, 1905. The knee-jerks were present, the pupils were normal, and the optic discs were of good colour. Vision = $\frac{6}{6}$. There was slight hyperopic astigmatism. The patient was constipated and occasionally she wetted the bed at night. There were rhagades about the mouth. The third sister, aged 23 years, I had no opportunity of examining.

CASE 3.[3]—The patient, a girl, 14 years of age, attended the out-patient department of the Kensington General Hospital for the first time on Feb. 26th, 1908. The personal history of the case showed that nothing was known to be amiss with the patient's sight *until she reached the age of ten years,* when the school teacher sent to say that the child was unable to see well. She was sent to school at the age of four years and during her school life, which terminated *recently, she was a dull child. She reached, however, the* fifth school standard. Upon the complaint of bad sight she was taken on Oct. 14th, 1903, to the Royal London Ophthalmic Hospital, Moorfields, where spectacles were prescribed and these were worn for about a year without any particular benefit. On Oct. 20th, 1904, the patient attended the Royal Westminster Ophthalmic Hospital, the out-patient letter belonging to which I have inspected. Her sight was then less than $\frac{6}{60}$ with either eye and a diagnosis of "post-neuritic atrophy" was marked on the sheet. Spectacles (plus 1 D. spherical) were prescribed for reading, but, again, they gave little help. The child made three attendances at the hospital in question during January last and was treated with a mixture containing iron and strychnine. When admitted to the Kensington General Hospital, the patient was found to be a well-grown but rather dull girl who had not yet begun to menstruate. R.V. = < $\frac{6}{60}$. L.V. = < $\frac{6}{60}$. The optic discs were pallid and cupped. They presented all the appearances of so-called "simple atrophy"—that is to say, they were *clearly defined*, the markings of the lamina cribrosa could be made out, the retinal vessels were of good size, and the surrounding retina showed no morbid changes. There was no choroiditis or perivasculitis; no fine vessels could be found in the corneæ. The visual fields for white (estimated by means of a 10 millimetre white square) were very small, especially in the left eye, where the field did not exceed 10° in any direction. In the right eye the limits were: externally, 18°; internally, 15°; above, 19°; and below 5°. The pupils, five millimetres, although sluggish to light, reacted promptly and well to accommodation. In other words, a potential Argyll Robertson pupil was present. The girl showed no ataxy, but she easily tired. Romberg's sign was not present. The bowels were regular without recourse to medicine. There was an imperative desire to urinate. The right knee-jerk could not be elicited, even on reinforcement; an occasional jerk could be obtained from the left knee. The ankle-jerks were absent. There was no ankle-clonus and Babinski's sign was absent. No definite account could be got of "lightning pains."

The diagnosis in the foregoing case rests mainly upon: (1) the state of the optic discs and of the pupils; (2) the absence of one knee-jerk and the impairment of the other; and (3) the imperative desire to urinate. It is not a typical case, but on any other view than that of juvenile tabes, it is difficult to account for the bilateral optic atrophy, which, clinically at all events, is now certainly not post-neuritic in character, whatever it may once have been.

With regard to the family history, the patient's mother, aged 44 years, was in good health. Her father, aged 44 years, was said to be a strong man in rude health. The *mother had had two miscarriages.* Seven children had been born alive, of whom the patient was the third. Three of the children had died—one at the age of one year from pneumonia; one at two years of age from phthisis pulmonalis; and the third at the age of three months from bronchitis.

The case to be next described differs from those already mentioned, since amblyopia was not its prominent feature.

CASE 4.—The patient, a boy, aged 11 years, was first seen at the Kensington General Hospital on August 1st, 1906. *The personal history showed that two years previously the* lad had suffered from "rheumatics" affecting the toes, the fingers, the knees, and the elbows, and he was confined to the house on that account for two and a half months. In May, 1905, the patient had complained of the right eye, which was observed to water, to be inflamed, and "to have a white look." In the following month the other eye became slightly affected. In October, 1905, the right eye was noticed to squint inwards. In January, 1906, there was a second attack of "rheumatic" nature, less severe than the first one. No history of symptoms pointing to congenital syphilis as a baby could be obtained. The family history showed that the patient's father (33 years of age) and mother (40 years of age) were both alive. The mother had had three miscarriages and two living children, of whom the patient was the elder. The other child, a boy, died from "convulsions" when aged one month. When the patient was seen at the hospital the facies and the upper central incisors were suggestive of inherited taint. The molars were decayed. *There was some thickening of the joints of the* first and second fingers of each hand between the metacarpus and the phalanges. There were interstitial opacities, together with Hirschberg vessels, especially of the right cornea. R.V. = < $\frac{6}{60}$. L.V. = $\frac{6}{9}$ partly. The left pupil (the *only* one that could be examined satisfactorily) was three millimetres in transverse diameter, and had extremely slight action to light but fair response to accommodation (incomplete Argyll Robertson phenomenon). The left knee-jerk was absent; the right knee-jerk could be obtained only on reinforcement. There had been, and still was, some slight urinary trouble when in bed at night—"a weak bladder," so the mother said.

In the last case to be mentioned the diagnosis is not quite so clear as in those already recounted. Indeed, it is possible, I suppose, that we were dealing not with juvenile tabes dorsalis but with an instance of hereditary cerebellar ataxy.

CASE 5.—The patient, a boy, aged ten years, attended the *out-patient department* of the Queen's Hospital for Children, Hackney-road, London, on June 21st, 1906. He presented a specific facies, with flattened bridge of the nose and characteristic upper central incisors. Abundant pus could be *squeezed from the left* lacrymal sac. R.V. = $\frac{6}{24}$. L.V. = $\frac{5}{60}$. There were nystagmus, especially on lateral movement, and simple optic atrophy, especially in the left eye. The retinal vessels were small. No choroiditis or other *ocular stigmata of syphilis could be traced.* The pupils were 3·5 millimetres in diameter and active to light. An occasional response only could be obtained from the knees on repeated stimulation with reinforcement. There was no *clonus, Romberg's sign* was absent, and there were no "lightning pains." Beyond a tendency to flat-foot there were no deformities. The child was an orphan and hence no family or personal history worth mentioning could be obtained.

Welbeck-street, W.

IN recognition of his researches into paludism the Société de Pathologie Exotique of Paris has on the nomination of Professor Laveran, the President, elected Dr. Ian Macdonald, Huelva, Spain, a corresponding member. The membership is limited to 70. Dr. Macdonald is a graduate of the Universities of Edinburgh and Paris.

[3] This patient was shown on March 20th, 1908, before the Society for the Study of Disease in Children.

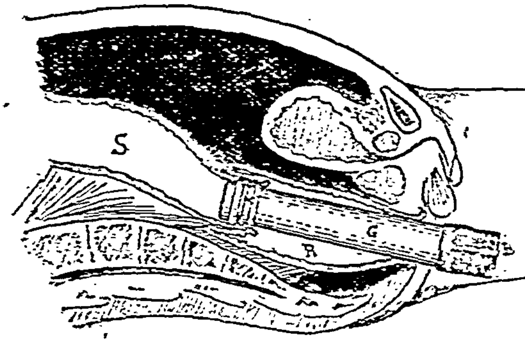
A NEW METHOD OF RESTORING THE CONTINUITY OF THE BOWEL IN CASES OF EXCISION OF A GROWTH LOW DOWN IN THE SIGMOID FLEXURE.

BY J. P. LOCKHART MUMMERY, F.R.C.S. ENG.,
HONORARY SURGEON TO KING EDWARD VII. HOSPITAL; ASSISTANT SURGEON TO ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM AND TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN.

MOST surgeons have experienced the difficulty there often is in restoring the continuity of the bowel after removing the lower part of the sigmoid flexure for cancer or other forms of disease. In many cases the growth is situated in the lowest part of the sigmoid flexure, just above the recto-sigmoidal junction and behind the bladder. In such cases, after an adequate portion of bowel has been removed, it is extremely difficult to deal with the ends, as the lower stump of bowel or upper end of the rectum is situated so deep in the pelvis that any ordinary form of end-to-end anastomosis is out of the question, and the only alternatives left are either (1) to close or pack off the upper end of the rectum and establish an artificial anus with the upper end of the sigmoid flexure; or (2) to proceed to remove the whole rectum by the abdomino-perineal route, and bring the end of the sigmoid flexure (if the mesentery is long enough) down to the anus. The first of these methods has the objection that it leaves the patient with a permanent colotomy, and the second that it entails a most severe and prolonged operation, and also means the removal of a perfectly healthy rectum, which if the continuity of the gut could be restored would be quite as useful as before. This being the case, I think the following method of restoring the continuity of the bowel in such cases without removing the rectum will be found useful. I have not been able to find any record of a similar operation having previously been performed. In the case here recorded all but a few inches of the sigmoid flexure had to be removed, and consequently it would not have been possible to bring the stump to the anus, and the only alternative to what was done would have been the establishment of a permanent artificial anus.

I first saw the patient, a man, aged 53 years, with Mr. W. McMullen of Brixton, on Oct. 18th, 1907, on account of hæmorrhage from the bowel. His history was that for nearly 12 months he had been passing mucus and occasionally blood and had had attacks of pain in the abdomen. For the last few months there had been a watery discharge which had been tinged with blood on one or two occasions. About a month previously he had a profuse hæmorrhage from the bowel and this had occurred again the day before I saw him, and had been accompanied by severe pain in the abdomen lasting for about half an hour. There was no history of constipation, and except for the present illness he had always been a healthy man. On examination per rectum nothing abnormal could be felt, but very high up a large resisting mass could be felt through the anterior rectal wall. Examination of the abdomen revealed nothing abnormal. I advised an examination under an anæsthetic and for this purpose he went to St. Mark's Hospital on Oct. 28th. Under ether, by bimanual examination, and after stretching the sphincters so as to allow of two fingers being inserted into the rectum, a growth could be distinctly felt in the lower part of the sigmoid flexure. This diagnosis was confirmed by sigmoidoscopy. It was decided that the growth was freely moveable and that if the patient agreed an attempt should be made to remove it.

The operation was performed on Nov. 4th. The patient was anæsthetised by Mr. H. Bellamy Gardner with ether by the open method. The patient having been placed in the Trendelenburg position, an incision was made through the outer part of the rectal sheath on the left side of the abdomen and extending right down to the pubes. On opening the abdomen I found that the lower part of the growth extended down to within one and a half inches of the recto-sigmoidal junction and that a loop of the sigmoid flexure above the growth had become adherent to, and was involved in, it. This necessitated the removal of all but a few inches of the sigmoid flexure if the growth was to be removed. The sigmoid flexure was divided above the involved loop and the meso-sigmoid was stripped up from the posterior pelvic wall and the vessels clamped as they were divided. This procedure was rendered necessary owing to the fact that some of the glands in the meso-sigmoid were involved. As a result of the stripping up of the peritoneum the great iliac vessels were laid bare. The sigmoid flexure at the recto-sigmoidal junction was now divided an inch below the growth and the adherent loops were removed. The peritoneum was brought together by stitches over the posterior pelvic wall and all bleeding points were ligated. At this stage, owing to the rectum not having been properly emptied previously to the operation, some soiling of the pelvic peritoneum unfortunately took place. Any of the ordinary methods of end-to-end anastomoses were quite impossible owing to the depth of the wound and to the fact that there was no stump of bowel below but merely a hole in the pelvic floor. I tied a glass Keith's tube into the upper end of the sigmoid flexure and passed the free end of this tube, to the end of which a piece of large-bore rubber tubing had previously been attached, down into the rectum from the abdominal cavity. An assistant then caught this with forceps introduced per anum and drew it out of the anus. By drawing on the Keith's tube the upper end of the sigmoid flexure was invaginated into the upper end of the rectum so as to form a kind of intussusception. Two or three silk stitches were then put in to prevent the invagination from coming undone. A drainage-tube was then inserted and the abdominal wound was closed in separate layers. The operation, which had taken some time, was well borne and there was no shock.



S, Sigmoid. R, Rectum. G, Glass tube to the upper end of which the sigmoid is tied. B, Piece of rubber tube to prevent glass tube from slipping up into rectum.

The patient was kept on a diet of albumin for the first week and sufficient fat "in the form of cream" was added to the feeds to keep the stools quite fluid. The bowels were freely opened with calomel on the third day through the tube. The tube separated and came away on the seventh day. After the tube came away a fæcal fistula formed along the track of the drainage-tube and there was some discharge for a time, but the bowels continued to act by the rectum. The patient made a good recovery without any bad symptoms and although the fæcal fistula was a troublesome complication it soon began to close and in the course of a couple of weeks only allowed a little flatus occasionally to escape and at the time he left the hospital was almost healed. He had complete control over the action of the bowels and defæcation was quite normal.

It was not possible with a finger in the rectum to feel the line of union, but an examination with the sigmoidoscope before he left the hospital enabled us to see it. There was no appreciable narrowing at the point of union and beyond a faint white line nothing could be seen.

I have since heard that the slight sinus which he had when he left the hospital has quite healed up and that he is now well.

The condition produced was practically a short artificial intussusception, the two peritoneal coats being in apposition and the ends of the mucous coats close together, though not necessarily touching each other. Owing to the glass tube tied into the upper portion of the bowel no leakage could occur and the ends of the bowel had about a week in which to become united to each other before there was any possibility of any strain being thrown upon the line of union; while the tube was still in position the bowels could be freely opened without any risk of leakage and this was a very great advantage in the case of an anastomosis so near the rectum.

I think this method of restoring the continuity of the bowel after resection of the whole or part of the sigmoid flexure and when no adequate lower stump of bowel is obtainable should prove useful, as it is a great improvement upon the more usual method of establishing a permanent colotomy. And it should be quite as safe, as the condition is for all practical purposes a colotomy during the first week after the operation.

One of the chief advantages of this operation is that it enables the continuity of the bowel to be restored satisfactorily in a situation where stitching is out of the question. Another great advantage is that the bowels can be freely opened on the day after the operation if necessary, without any fear of rupture or leakage or any danger of soiling the peritoneum, as the sigmoid flexure and tube are continuous and gas-tight. The fact that apposition between the two ends of the bowel is not very accurate does not matter, in view of the fact that no strain at all is thrown upon the line of union for nearly a week after the operation owing to the presence of the glass tube. I was doubtful at first if the presence of a long glass tube in the rectum would cause severe pain or other trouble, but beyond some swelling of the anus there was no pain or other inconvenience from the presence of the tube. In the future, however, I shall use a specially made rubber tube in place of the glass one. These special tubes have a hardened grooved end and have been made for me by Messrs. Allen and Hanburys.

The formation of a fæcal fistula in this case I attribute to the fact that the nurse had not got the rectum empty and in consequence, the patient being in the Trendelenburg position, the peritoneum became soiled directly the bowel was divided.

Cavendish-place, W.

THE DIAGNOSIS OF PERFORATING AND OF CHRONIC DUODENAL ULCER.[1]

BY SIR JOHN F. H. BROADBENT, BART., M.D. OXON., F.R.C.P. LOND.,

PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL; AND ASSISTANT PHYSICIAN TO THE LONDON FEVER HOSPITAL.

OF recent years attention has been directed to the subject of duodenal ulcer, more especially in reference to sudden perforation of the ulcer. A correct diagnosis of this condition is more commonly arrived at now than was the case some eight years ago, when in a paper by Dr. Weir[2] of New York out of 51 cases collected by him a correct diagnosis was arrived at in only 13 instances, the condition being mistaken most commonly for appendicitis or perforated gastric ulcer, and in some instances for intestinal obstruction. Since that date numerous papers have been published on this subject by various authors.

In this communication, while referring to the question of perforation, I purpose more particularly to deal with the symptoms of non-perforating ulcer and its *sequelæ*, the diagnosis of which is often a matter of considerable difficulty.

Etiology of Duodenal Ulcer.

Burns are mentioned in surgical text-books as a cause of duodenal ulcer. Holmes[3] records the occurrence of duodenal ulcer in 16 out of 165 cases of burns. Collin[4] found it present in 38 out of 297 cases collected. Perry and Shaw met with it in five cases out of 149 collected from the Guy's Hospital post-mortem records. Various explanations have been suggested for this association of duodenal ulcer with burns. The most plausible would seem to be that the congested condition of the intestines is the predisposing, and septic embolism or thrombosis of a small vessel followed by digestion of the necrotic area the determining, cause. Burns are, however, present in only a very small proportion of cases and cannot be regarded as important etiological factors.

It is noteworthy that while gastric ulcer is most frequently met with in young anæmic women, by far the greater proportion of duodenal ulcers, 79 per cent. according to Collin's statistics, occur in strong middle-aged men and are not associated with anæmia. Tobacco and alcohol, to which men are more addicted than women and which are supposed to intensify the acidity of the gastric juice, have therefore been thought to predispose to duodenal ulcer. There is certainly a history of alcoholism in a large number of cases, but so few comparatively out of the vast number of alcoholics and heavy smokers suffer from duodenal ulcer that this is scarcely an adequate explanation for its preponderance in men. Possibly the constant stooping and lifting associated with laborious occupations combined with irregular meals and coarse food may play some part in its production, for it is more frequently met with in the working classes.

Ulceration occurs most frequently in the first part of the duodenum which is exposed to the action of the acid gastric contents before they are neutralised by the alkaline flow of pancreatic juice and bile. It would seem most rational therefore to attribute duodenal ulcer to the same causes as gastric ulcer—namely, the solvent action of the hydrochloric acid secreted by the stomach on a portion of tissue the vitality of which has been lowered by traumatism or by the cutting off of its blood-supply by embolism or thrombosis. Anatomically it resembles a gastric ulcer. It may be punched out with sharp clean-cut edges, and perforate suddenly without previous warning, or the edges may be thickened and heaped up so that the ulcer presents a funnel-shaped appearance. Adhesions may form between the inflamed peritoneum at the base of the ulcer and adjoining structures, or cicatricial contraction occur with resulting narrowing of the lumen of the duodenum. Not infrequently more than one ulcer is present.

Perforation of Ulcer.

The duodenum is so situated anatomically, being deeply placed behind the right lobe of the liver and the gall-bladder, that when perforation of an ulcer takes place the contents of the gut do not as a rule escape directly into the general peritoneal cavity, as is the case in perforation of a gastric ulcer. More commonly the escaped fluid tends to travel along the posterior aspect of the hepatic flexure of the colon, thence gravitate downwards to the front of the right kidney and eventually along the outer side of the ascending colon to the right iliac fossa, setting up peritoneal inflammation in its track, which may simulate renal trouble or appendicitis. Frequently the peritonitis is localised in the first instance to the right flank, so that the symptoms of collapse are not so marked as in gastric ulcer. Moreover, the duodenum is not like the stomach, a large sac full of fluid, but is only filled as the gastric contents flow into it during digestion, and it may be practically empty at the time of perforation, so that the extravasation is limited in amount.

Symptoms of Perforation.

Turning now to the symptoms of perforation, the common story is that a strong healthy-looking man while at work, lifting a heavy weight, or perhaps shortly after a meal, is suddenly seized with violent pain in the abdomen in the right epigastric or hypochondriac region, followed immediately or after a short interval by vomiting. Symptoms of collapse may set in almost immediately if general peritonitis results, but they are less severe as a rule than in perforation of a gastric ulcer and may be ill marked or deferred for some hours or even be absent altogether. For, as has already been said, the resulting peritonitis is frequently limited to the right side of the abdomen. There will then be pain, tenderness, and rigidity in the right flank, and the tenderness may be marked not only in front but in the loin behind the right kidney. The movement of the abdomen in respiration will be restricted, more especially on the right side. The temperature will be raised to perhaps 101° or 102° F., the pulse-rate increased to 100 or 112, and the aspect of the patient will be characteristic of abdominal trouble. The prognosis for operation at this stage will be good, but if deferred too long the peritonitis may become general by the breaking down of adhesions, or failing this a subphrenic abscess may result from extravasation upwards between the right lobe of the liver and the diaphragm.

The following three cases illustrate (1) localisation of the peritonitis to the right flank; (2) general peritonitis; and (3) formation of subphrenic abscess.

CASE 1.—A man, aged 31 years, was admitted under my care while in charge of the wards to St. Mary's Hospital on August 21st, 1906, complaining of severe pain in the right hypochondriac region. He said that he had been quite well till two days before admission when he was seized while at work with severe pain in the right hypochondriac region and vomiting about one hour after his dinner. The pain became more severe next day, and the

[4] Thèse de Paris, 1896.

vomiting persisted. Previously to this attack there was no history of pain or indigestion in any form. He had been a fairly heavy drinker. On admission the face was flushed and anxious, the pulse was 100, and the temperature was 101° F. There were tenderness and rigidity in the right flank, most marked behind in the lumbar region. There was immobility of the right upper segment of the abdomen in respiration, but elsewhere the abdomen moved fairly well and there was no general tenderness or rigidity. From the sudden onset of the pain and vomiting and the evidence of some inflammatory trouble in the right upper quadrant of the abdomen I diagnosed perforation of a duodenal ulcer. From the localisation of the tenderness and rigidity to the right lumbar region I thought it was probable that the contents of the duodenum had gravitated downwards along the colon to the front of the right kidney. I therefore asked Mr. W. H. Clayton-Greene to operate and suggested that he should explore the right flank and cut down on the right kidney. Nothing was found extra-peritoneally, but on incising the peritoneum an abscess was found immediately in front of the kidney from which about two ounces of pus were evacuated. The abscess was localised and shut in by adhesions, so no attempt was made to suture the ulcer in case the breaking down of adhesions might lead to infection of the general peritoneum. A drainage-tube was inserted and the patient made a rapid and excellent recovery.

CASE 2.—A man, aged 26 years, was admitted to St. Mary's Hospital on August 24th, 1900, being sent as a case of appendicitis. He stated that he was quite well till the day before. He was then lifting a heavy weight when he was suddenly seized with severe pain in the abdomen, followed by vomiting. He was brought to the hospital on the next day. On admission he was collapsed, the face was pinched, pale, and anxious, the temperature was 99° F., the pulse was 124, and the respirations were 36. The abdomen was distended and scarcely moved in respiration, there were tenderness and some rigidity in the right epigastric region, and the legs were drawn up. The liver dulness was absent and on tapping two coins together and auscultating over the liver area there was a well-marked bell note. There was occasional hiccough but no vomiting. Mr. H. S. Collier operated at once. On opening the abdomen free gas escaped and there was recent general peritonitis. A perforated ulcer was found in the first part of the duodenum, and was sutured. The patient was, however, in an almost desperate state and he died the same evening. At the necropsy there were recent general peritonitis and a small collection of pus between the liver and the diaphragm. In the duodenum about one inch from the pylorus were three ulcers, one of which had perforated and had been sutured.

These two cases were fairly straightforward and the diagnosis did not present any great difficulty. When, however, a subphrenic abscess results from formation of adhesions and the case is not seen till some days or weeks after the perforation has taken place the diagnosis may present considerable difficulty as the following case will illustrate.

CASE 3.—A man, aged 60 years, was admitted to hospital under the care of Dr. W. B. Cheadle on March 16th, 1900. He said that he was taken ill suddenly five weeks previously with severe pain in the right side of the abdomen, followed by vomiting. He went to bed and stayed there a week, when he got up again, but a few days later was seized with severe pain in the left side of the abdomen, vomited, and had several rigors. He remained in bed and had only had liquid food for the last week, but cough and increasing dyspnœa compelled him to go to the hospital. On admission he was pale and emaciated, with an anxious expression and very short of breath. The pulse was 140, the temperature was 101·8° F., and the respirations were 34. The abdomen was distended and tympanitic and did not move freely in respiration. There were signs of effusion in the left pleural cavity. The heart was somewhat displaced; otherwise it was normal. An exploring needle was inserted below the angle of the left scapula and offensive pus was withdrawn. A diagnosis of empyema was made and he was taken to the theatre. A portion of rib was resected just below the puncture of the exploring needle, and a quantity of clear serous fluid escaped from the left pleural cavity. The patient was too ill for further exploration and was put back to bed. He died at 3 P.M. on the next day. At the necropsy a large subphrenic abscess was found bounded above by the diaphragm, below by the upper surface of the liver and stomach, and to the left by the spleen, which was riddled with small abscesses. It was shut off from the general peritoneal cavity by adhesions, but the pancreas was gangrenous and almost entirely destroyed. There were *two ulcers in the duodenum*, one of which had perforated and given rise to the subphrenic abscess.

In this case the perforation had apparently taken place five weeks before admission, when the patient was attacked with sudden pain in the right side, followed by vomiting. This was thought by his medical man to be an attack of biliary colic. The leakage had been apparently small and was circumscribed by adhesions which were broken down when the patient got about again and led to extensive suppuration and a subphrenic abscess. The most prominent symptom on admission was extreme dyspnœa, which seemed to be accounted for by extensive pleural effusion. The exploring needle when inserted must have gone through the pleura into the subphrenic abscess which pushed up the diaphragm, since offensive pus was withdrawn, and the subsequent discovery of clear fluid when operating for empyema came as a surprise. It is, however, by no means uncommon to find clear fluid in the pleural cavity in association with suppuration beneath the diaphragm and I have seen it in two other instances with subphrenic abscess and in one case with a liver abscess. I am indebted to Dr. Cheadle for permission to publish these two cases, which I had the opportunity of seeing when medical registrar.

Chronic Ulcer of the Duodenum.

The symptoms and physical signs that may be present in this affection are:—

Pain, usually felt in the right epigastric or right hypochondriac region but sometimes not localised to any particular spot, is one of the most constant symptoms and may persist on and off for some years. It may be slight and be ascribed to "indigestion," or it may be severe and described as gnawing, sharp, or griping in character. Sometimes it is paroxysmal and may be attributed to biliary colic, as in one case I saw in which attacks had persisted on and off for five years. It is not, as a rule, immediately induced or aggravated by ingestion of food, as in gastric ulcer, but may be relieved thereby, as the closure of the pylorus which ensues will temporarily arrest the flow of gastric contents into the duodenum. It may set in an hour or two after meals but frequently the patient does not notice any definite interval or even any causal relation between the taking of food and the onset of the pain. Sometimes it may be almost constant day and night as a dull aching pain with exacerbations at irregular intervals.

Vomiting, which is a comparatively rare antecedent of perforation (it was present in only 17 per cent. of the cases of acute perforation collected by Weir), is, I think, a fairly constant feature in cases of chronic duodenal ulcer. It was present at one time or other *in all the cases which I have seen.* It is not always persistent or frequent but may occur at irregular intervals without any special relation to meals. Sometimes it appears to afford relief to the pain by emptying the stomach, so that the flow into the duodenum ceases, so much so that a patient may put his finger down his throat to make himself sick. Large quantities may be vomited up at the end of the day when there is dilatation of the stomach induced by cicatrisation of the ulcer and narrowing of the duodenum.

Hæmorrhage is stated by Krauss to occur in about 33 per cent. of cases, but in 151 cases collected by Perry and Shaw it was noted in 23 only, or about 13 per cent. Both hæmatemesis and melæna may occur, but melæna is more significant when present alone, as when both are present it will be difficult to exclude gastric ulcer. My experience is that neither is very common. Hæmatemesis and melæna occurred in two and melæna alone in two out of the 12 cases on which this paper is based. In one of these the hæmorrhage recurred a year after the successful relief of all symptoms by gastro-enterostomy, so it is probable that the ulcer was really not in the duodenum itself but near the pyloric orifice of the stomach. It is possible that *melæna* may escape the notice of the patient, as he may not realise that the black, tarry motions which he passes *contain blood.*

The following case can be quoted as an instance of hæmorrhage. A man, aged 49 years, was brought to St. Mary's Hospital in July, 1905, with a history that he had fallen down in the street vomiting blood. On admission he was profoundly anæmic; the pulse was small and rapid, and after admission there was profuse melæna. He said that he had never vomited or passed blood before this attack, but for the last six years had suffered from indigestion and for the last two years had pain in the epigastrium almost constantly about an hour after meals. Nutrient enemata were administered and no food was given by the mouth for three days. A little peptonised milk was then given by the mouth but the hæmorrhage recurred, so recourse was again had to nutrients. As he was losing ground and getting weaker and thinner it was decided to perform the operation of gastro-enterostomy and on July 21st, a week after admission, this was done by Mr. Clayton-Greene. There was no thickening of the duodenum and no adhesions or any external evidence of an ulcer were to be seen at the operation, but the interior of the duodenum was not examined. He made a rapid and satisfactory recovery; there was no return of hæmorrhage and he was soon able to eat any kind of solid food without discomfort.

Dilatation of the stomach.—This I consider a symptom of considerable diagnostic importance. It may result from stenosis of the duodenum or pylorus by cicatrisation of an ulcer and there may be considerable thickening of the wall of the duodenum or scarring and puckering of its peritoneal surface, and in two cases of this nature I have observed well-marked peristalsis of the stomach wall. In some cases there are adhesions between the duodenum and adjacent structures or cicatricial bands which may give rise to obstruction, but in others in which dilatation of the stomach is present no obvious cause can be made out at the operation for gastro-enterostomy when this is performed. Of course the interior of the duodenum is not investigated in those cases, and it is possible that some narrowing of the lumen is present. In two fatal cases, however, I have found marked dilatation of the stomach in which at the necropsy no stenosis of the duodenum could be made out. In one of these three ulcers were present. It seems possible, therefore, that the dilatation of the stomach may be gradually brought about by reflex spasm of the pylorus, due to a reflex inhibition of its dilating mechanism, when the gastric contents begin to flow over the ulcerated surface. If so, this would explain the presence of dilatation of the stomach in those cases in which at the operation no thickening of the duodenum or definite evidence of obstruction can be made out. Peristalsis of the stomach wall would only be expected to occur when definite obstruction had been produced by cicatricial contraction of an ulcer or adhesions. In the two cases in which I have observed it well-marked thickening and scarring of the duodenum were present.

The following cases illustrate dilatation of the stomach in association with chronic duodenal ulcer.

CASE 1.—A man, aged 48 years, went to my out-patient department at St. Mary's Hospital in August, 1907, complaining of vomiting large quantities of food, chiefly at night. There had been no pain after meals recently, but some time before he said he had attacks of "indigestion." There was no history of melæna or hæmatemesis. He had not been a heavy drinker but had taken his two or three pints of beer daily. There was great dilatation of the stomach, which extended well below the umbilicus, as ascertained by the combined succussion and auscultation method. He was admitted to the hospital on Sept. 7th and when in bed well-marked peristalsis of the stomach from left to right was observed on several occasions. This was well brought out by the administration of bicarbonate of sodium and tartaric acid. On washing out the stomach and testing its capacity it was found to hold 102 ounces. No tumour could be felt in the region of the pylorus and there was no tenderness in that region. The symptoms and physical signs clearly pointed to dilatation of the stomach from obstruction at or just beyond the pylorus, so I decided on the operation of gastro-enterostomy for its relief. Mr. Clayton-Greene performed the operation on Sept. 19th. At the operation the stomach was seen to be enormously dilated and its walls were hypertrophied. There was no thickening of the pylorus but there were numerous adhesions in the neighbourhood of the duodenum and scarring of its peritoneal wall. The patient subsequently made an uninterrupted recovery. There was no more vomiting and he rapidly gained weight and went out feeling quite well.

In this case there was no evidence of definite symptoms pointing to duodenal ulcer except that of some "indigestion" a long time before, but from what was seen at the operation it was clear that cicatrisation of a duodenal ulcer and inflammation of its peritoneal surface were the cause of the dilatation of the stomach to which the symptoms pointed when he came for treatment.

The next three cases are very similar to the above.

CASE 2.—A man, aged 33 years, was admitted to St. Mary's Hospital in September, 1907, while I had charge of the wards. He said that he had had attacks of pain in the right epigastric region and vomiting on and off at intervals for the last five years, sometimes being free from them over a month at a time. Vomiting relieved the pain but neither the onset of vomiting nor the pain bore any direct relation to ingestion of food. There was no history of melæna or hæmatemesis. He was not addicted to alcohol. The stomach was very dilated, a succussion splash being audible below the umbilicus. There was no tumour to be felt at the pylorus and peristalsis was never observed. No tender area could be detected on palpation. A test-meal showed the presence of free HCl, the acidity being estimated at 0·024 per cent. of free HCl by Dr. W. H. Willcox. On Nov. 8th Mr. V. W. Low performed the operation of gastro-enterostomy. There were no thickening of the pylorus or duodenum and no scarring or puckering and only a few adhesions were found in the neighbourhood of the latter. The patient had no return of the pain or vomiting and made a rapid recovery.

In this case no obvious obstruction could be made out in the duodenum at the operation and little evidence of ulcer from the exterior but there could be no doubt that a duodenal ulcer was the cause of the symptoms and of the gastric dilatation.

CASE 3.—Three years ago I was asked to see in consultation a man, aged 40 years, who for six years had suffered from "dyspepsia" and who during the last six months had had severe pain in the right epigastric and hypochondriac region usually about half an hour after meals. During the last three months he had vomited enormous quantities at intervals, chiefly at night. He was very emaciated and had rapidly lost flesh of late. There was no history of melæna or hæmatemesis. On examination I found enormous dilatation of the stomach. There was no tumour in the pyloric region but an area of tenderness on palpation under the right costal margin. I advised the operation of gastro-enterostomy which was successfully performed. There were adhesions and considerable thickening of the duodenum. He made an excellent recovery and in two months gained a stone in weight and is now in excellent health and has had no return of symptoms.

CASE 4.—In October, 1906, I was asked to see a lady, aged about 35 years, who for three months had had pain in the left epigastrium and irregular attacks of vomiting of large quantities of food. Four years previously she had had hæmatemesis and melæna and since then she had had at intervals attacks of pain and vomiting. On examination the stomach was found to be enormously dilated and on several occasions well-marked peristalsis of the stomach wall was observed. I concluded that the dilatation was due to obstruction in the duodenum from a cicatrised ulcer and advised the operation of gastro-enterostomy, which was successfully performed. This I did not see, but I was informed after that there were a mass of adhesions in the neighbourhood of, and considerable thickening of, the duodenum, giving rise to considerable obstruction. She made a good recovery.

The following case illustrates the chronicity of the affection and the tendency to recurrence even when the symptoms have been in abeyance for some considerable period of time.

CASE 5.—A man, aged 52 years, went to my out-patient department at St. Mary's Hospital on Jan. 3rd, 1908, complaining of pain in the right epigastric region and attacks of vomiting. His history was as follows. Ten years ago he was first troubled with "indigestion," pain in the epigastric region some two or three hours after meals, with occasional attacks of vomiting. This persisted on and off for six years when he had a severe attack of melæna. As a result of careful dieting, complete rest, and change of air his symptoms completely disappeared and he enjoyed good health for about six months. The pain and vomiting then recurred and had persisted on and off for the last four years. Latterly the pain had become more or less constant and the vomiting, instead of setting in a few hours after meals, had occurred chiefly at night and was more profuse. He had been losing flesh rapidly of late and dieting failed to relieve the symptoms. He was a strong, well-made man but very poorly nourished and was strictly temperate. On examination the stomach was found to be greatly dilated and there was some tenderness on deep pressure just below the seventh right costal cartilage. No tumour could be felt. From the history of the case, attacks of pain and vomiting extending over nearly ten years, melæna, and symptoms which now pointed to some obstruction at or beyond the pylorus, with pain in the right hypochondriac region, I diagnosed chronic duodenal ulcer, partial cicatrisation of which was giving rise to stenosis of the duodenum and consequent dilatation of the stomach. I therefore advised the operation of gastro-jejunostomy which Mr. Low successfully performed on Jan. 10th. At the operation a few adhesions were found in the neighbourhood of the duodenum and a small hard cicatrix was felt on the anterior aspect of the first part of the duodenum. There was no recurrence of vomiting after the operation and he is now free from pain and able to take food without any pain or discomfort.

Diagnosis.—An accurate diagnosis can usually be made by careful consideration of the history of the case and the chronic character of the symptoms rather than by physical signs, which are often very indefinite. In a typical case the patient will be a middle-aged man with a history that he has suffered on and off for some years with pain and vomiting. He may tell you that at first the pain usually set in from two to three hours after meals and was sometimes temporarily relieved by taking food or by vomiting. Vomiting sometimes accompanied the pain but was not so constant or persistent a symptom. These symptoms were not so severe as to compel him to leave off work and as a result of careful dieting they may have been in abeyance for weeks at a time, but they tended to recur on resuming ordinary diet. He may have sought advice because they have been increasing in severity and the pain has become more or less constant and is not relieved by dieting. Possibly neither the pain nor vomiting now has any direct relation to ingestion of food, and there may be no definite area of tenderness on palpation of the abdomen. Here the diagnosis must be based mainly on careful consideration of the history and chronicity of the symptoms.

A severe attack of melæna or of melæna and hæmatemesis may have brought matters to a crisis. In this event there can be little difficulty in arriving at a correct diagnosis. Again, the patient may say that recently the symptoms have altered in character, that the pain is less or is now griping in character instead of sharp and gnawing or has disappeared, and that the vomiting now comes on at night or every two or three days and a very large quantity is brought up each time. Examination will reveal considerable dilatation of the stomach and it may be that on careful inspection peristalsis of the stomach wall is observed. The presence of these physical signs with a history such as that given above will leave no doubt as to the correct diagnosis. If the ulcer be cicatrised completely there will be no pain and the previous symptoms may have been almost forgotten, but if there be only partial cicatrisation or fresh ulcers have succeeded one already cicatrised, pain will be present and perhaps deep-seated tenderness on palpation below the seventh costal cartilage.

Differential diagnosis.—The seat and character of the pain, the indefinite relation of both pain and vomiting when this occurs to ingestion of food, and the absence of hæmatemesis will, as a rule, serve to distinguish duodenal from gastric ulcer. Hæmatemesis and melæna may occur but the former is comparatively rare. Melæna in association with attacks of pain in the right hypochondriac region will be very significant. A history of chronic indigestion occurring after middle life may suggest malignant disease of the stomach, but the chronicity and intermittent character of the symptoms which may have lasted some years, and absence of severe emaciation and cachexia, will usually enable an accurate diagnosis to be made. In doubtful cases the evidence afforded by a test meal will be of great value, as in duodenal ulcer there is often excess and seldom absence of free hydrochloric acid. When gastric dilatation is present and peristalsis shows evidence of obstruction at or beyond the pylorus, the question of new growth of the pylorus must be considered. The absence of any tumour in the pyloric region, and the history of attacks of vomiting and pain on and off for some months or years in the right epigastric or hypochondriac region will usually enable a diagnosis to be made between these two affections. It will be advisable in all cases before considering operation to remember to exclude the possibility of gastric crises from tabes dorsalis.

Treatment.—There can be no question that the only satisfactory method of treatment as soon as a diagnosis is arrived at is by the operation of gastro-jejunostomy. This, of course, short-circuits the duodenum and usually all symptoms subside rapidly after the operation; the result is, as a rule, most satisfactory. Rectal feeding for some days and subsequent careful dieting may give relief and apparently are successful in some cases, but it must be remembered that there is a tendency for the ulcer to recur and that even when the ulcer does heal satisfactorily cicatricial contraction may give rise to obstruction and lead to gastric dilatation for which the same operation will eventually be required.

Seymour-street, W.

A METHOD OF ADMINISTERING SOLIDS IN CASES OF GASTROSTOMY.

BY A. ERNEST MAYLARD, M.B., B.S. LOND.,
SURGEON TO THE VICTORIA INFIRMARY, GLASGOW.

THE desirability of administering as much nutritious food as possible and the difficulty usually of doing so has led me to devise a method by which practically solid food can be introduced through the artificial fistula.

The operation employed is that known as the "Kader-Senn." It consists in bringing out a cone of the cardiac end of the stomach through a small parietal wound. The base of the cone is first fixed to the abdominal parietes by four silkworm gut stitches which in the course of a few days are withdrawn. A purse-string chromic gut suture is made to transfix the sero-muscular tunic of the stomach near the base of the cone. An opening is made at the apex of the cone and into this is inserted a glass tube (see Fig. 2) which has near its end two perforations to enable the tube and the stomach to be transfixed by a chromic gut suture. By then pushing on the tube the cone becomes invaginated and is finally secured by tightening the purse-string suture. The details of the operation will perhaps be better understood by a glance at the diagrammatic illustration (Fig. 1).

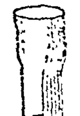

FIG. 1.—Diagrammatic representation of the operation of gastrostomy by the "Kader-Senn" method. *a*, Cone of stomach drawn out through an incision in the abdominal parietes (*f*. *b*, Gastrostomy glass tube with apertures at *c* for fixation by suture of the tube into the opening at the apex of the gastric cone. *d*, Purse-string suture for tightening after invagination of tube and cone. *e*, *e*, Two of the four silkworm gut sutures used for fixing the base of the cone to the abdominal parietes.

I have performed this particular operation 16 times with one death. The death occurred in a patient who was in an advanced emaciated condition and on the verge of dying. The shortest times in which I have performed the operation have been six minutes with the administration of an anæsthetic; and 12 minutes when only local anæsthesia to the skin was employed. In the former case I had the advantage of the able assistance of my colleagues, Dr. Farquhar Macrae and Dr. David Lamb, the infirmary anæsthetist. The patient was an old man, aged 79 years. A tight, probably malignant, stricture existed high up in the œsophagus, and in attempting to take fluids they trickled over into the larynx and caused violent attacks of coughing. He was much enfeebled and suffered from chronic bronchitis. Speed in operating was therefore of some moment. 15 minutes may be taken as a reasonable time for the performance of the operation. It need hardly be said that a method that lends itself to rapidity of performance is of no small consideration in the class of patients for which gastrostomy has most frequently to be employed.

The glass tube used (Fig. 2) measures 9 millimetres in its internal diameter and 12·5 millimetres in its external. This is sufficiently large to admit of the free introduction of solids held in fluid suspension and can be used either with or without the syringe. When the syringe is used alone the nozzle, which is about 9 centimetres long and of the same calibre as the tube (see Fig. 3), is introduced directly into the stomach. The food is then poured into the syringe, the piston is introduced, and gentle intermittent pressure is exercised to force in the food. When there is difficulty in introducing the nozzle of the syringe a vulcanite guide is inserted into the gastrostomy tube which serves to facilitate its passage and admit of the exercise of some pressure. The syringe holds about six ounces, and as a "feed" should consist of from 10 to 15 ounces it is necessary to refill the syringe. This is done by first withdrawing the cork and then inserting a knitting-needle by the side of the rubber ring. By pressing the former a little to one side and gently withdrawing the piston air gets in and prevents any backward suction of that which has already been introduced into the stomach.[1] After the withdrawal of the nozzle of the syringe or of the gastrostomy tube—whichever may have been used for the introduction of the food—a small plug is held over the orifice of the fistula for a minute or two, when it will be found that no leakage ensues.

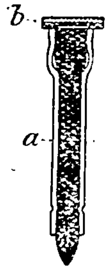

Fig 2

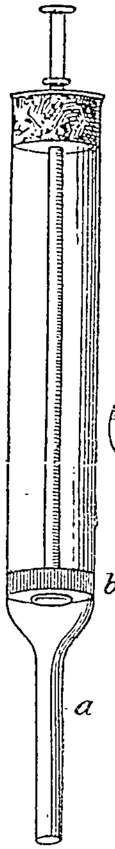

Fig 3

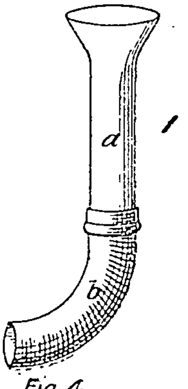

Fig 4

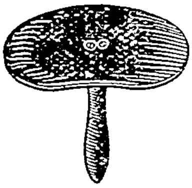

Fig. 5

FIG. 2.—Gastrostomy glass tube, *a*; with vulcanite guide, *b*.

FIG. 3.—Gastrostomy feeding syringe with cork above through which the piston rod runs. *b*, Rubber plug of piston rod. *a*, Nozzle of feeding syringe for direct insertion into the stomach or for use with the gastrostomy tube.

FIG. 4.—Glass filler, *a*, with rubber tube, *b*, for use with gastrostomy tube when syringe is not employed.

FIG. 5.—Vulcanite plug for use between periods of feeding and for the maintenance of a patent fistula.

In cases where the syringe is not used a considerable amount of solids, in, however, a more fluid consistency, can be introduced by means of a filler attached by a rubber tube to the gastrostomy tube (see Fig. 4). To insure the fistula being kept sufficiently patent for the introduction of the glass tube or syringe nozzle a specially shaped vulcanite plug (see Fig. 5) is employed. This is always worn between the periods of feeding.

The best consistency of the food for feeding is four ounces of finely divided solid to six ounces of fluid. Both constituents may be varied. One of the most nutritious combinations is chicken and milk. The point of paramount importance is the fine division of the solid, so that when being forced through the narrowed nozzle it does not pack and jam the canal.

The complete set of the requisites for the operation and after-use have been made for me by Messrs. Baird Brothers, 97, Bath-street, Glasgow.

Glasgow.

THE ELECTRICAL TREATMENT OF ATONIC CONDITIONS OF THE DIGESTIVE SYSTEM.[1]

BY REGINALD MORTON, M.D. TORONTO,
F.R.C.S. EDIN., &c.,
MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT OF THE LONDON HOSPITAL.

THE frequency with which atonic disorders of the digestive system are met with in medical practice makes the question of their treatment one of almost universal interest. Like all other fairly common disorders the list of suggested remedies is large and each one has its devoted advocates. It is not the purpose of this paper to discuss treatment by drugs and diet and their respective merits—these are more or less generally known and need not detain us, except to point out that the question of diet is all-important in every case, and to remind you that in the majority of cases the action of electricity is not so rapid that you can afford to discontinue drugs—e.g., laxatives—entirely and at once. Cases of atonic dyspepsia or constipation due to atony of the colon have always been under a more or less prolonged course of treatment and whatever electrical method is employed I always insist on the laxatives, &c., being continued as before. They are to be reduced in amount gradually as improvement sets in. For convenience I divide cases of atonic dyspepsia and constipation into two main classes: (1) those due to defective innervation—neurosis; and (2) those of true atony of the muscular coat of the digestive canal.

In the first class the muscular coat is presumably not at fault, and it is to the nervous system that we must direct our energies. For this purpose almost any form of electricity may be tried and with equally successful results, preference being given, in my opinion, to the more stimulating forms such as the induction coil currents and the sinusoidal current from the main or from a machine made for the purpose where the alternating current is not available. In many of these cases the moral effect is one of some importance, and for this reason good results are sometimes obtained from static electricity or high-frequency currents which may be more or less locally applied. The constant current alone I do not consider to be much good, but in conjunction with the coil—the de Watteville current, as it is sometimes called—it seems to be a very useful method and one that has achieved good results in the hands of some workers. Mangelsdorf[2] also claims to have obtained good results in the more severe cases of true atony of the muscular coat, but my experience does not bear this out. Provided one can remove any mental or psychological element that may be present in cases of this class the treatment becomes a comparatively simple matter, and one or other of the electrical methods mentioned will nearly always bring about a cure.

When we come to deal with cases of the second class we are brought up against an entirely different problem and one that will tax our resources to the utmost, as indeed it probably has that of the medical man who refers the case to us. Here we have to deal with an organ the muscular coat of which has undergone atonic changes even to an extent almost amounting to a degeneration. Regulation of diet has had little effect and drugs afford but temporary relief. Massage will have been tried with but slight success for reasons which are more or less obvious. At the same time, I *do not* mean to say that these methods are by any means useless—rather that we *should use electricity as* an additional agent in many cases, and, as I have already said, only to reduce the amount of drugs taken as *the case shows signs* of undoubted improvement.

---

[1] The syringes are now made with a small aperture at the lowest part which can be opened or closed as required, thus dispensing with the needle.

[1] A paper read before the Electro-Therapeutical Section of the Royal Society of Medicine on April 24th, 1908.

[2] Archives of Roentgen Ray, April, 1907.

In my opinion the person who sets out to treat a severe case of this kind with electricity only will most likely be disappointed chiefly on account of the slowness with which the improvement is brought about. From the very nature of the disease it is unreasonable to expect that any remedy can bring about a rapid cure. Having a case of this kind to treat the question arises, What are we going to do for it in the way of electrical applications? Every form of this agent has been tried at one time or another, and so long as this was confined to the more ordinary forms, such as constant and faradic currents, no very great success has been attained; so little, indeed, that until quite recently most writers on gastro-intestinal disorders ignore electricity altogether when discussing modes of treatment. That this should be so is not surprising. It is difficult to see how the use of the constant current could do very much; it is insufficiently stimulating, and its application in sufficiently large currents to influence materially the muscular coat of the digestive organs is attended by the risk of severe burns due to the deposition of electrolytic products in the skin.

Then take the induction-coil currents—primary or secondary—as ordinarily used I consider the rate of interruption much too fast to benefit the muscular tissue directly. In the case of degeneration in a voluntary muscle, as is well known, no reaction takes place when ordinary faradic current is applied unless the interrupter is set to work very slowly—the muscle can also be made to contract rhythmically to the constant current if it is made and broken equally slowly, the greater the degree of degeneration the less frequent must be the *interruptions if the* muscle is to respond to each. In unstriped muscle we have normally, to electrical impulses, a prolonged latent period and a prolonged period of contraction. In a state of atony these are increased and the condition, in my opinion, *comes to* resemble somewhat that of a voluntary muscle in a state of degeneration. Hence I consider ordinary faradic current to be unsuitable, both from the rapidity of its interruptions and the small density of current that could be obtained or used if obtainable. We must not forget that we can reach the intestinal muscle only through the more superficial voluntary muscles of the abdominal walls, which are necessarily thrown into contraction, and this latter becomes unbearable to the patient if the current density is at all high. The same objections apply to the sinusoidal current at the frequencies ordinarily supplied —from 40 to 100 cycles per second. While it is possible to set the interrupter of an induction coil to work very slowly even then only a comparatively small current density can be employed owing to the painful nature of the contractions produced when this is large. This is, of course, mainly due to the inherent qualities of the current itself, notably to the very sudden rise of potential at each *break* of the primary circuit.

From what has been said it will be seen that what we *require is a current* of large magnitude, in view of the large mass of the abdominal contents to be treated, and one that will vary this magnitude sufficiently rapidly to cause the muscular coat of the intestine to contract and yet slowly enough to allow a *contraction to be* completed and relaxed before another is induced. It must also be practically free from the deposition of electrolytic products in the skin to any possibly *harmful* degree. These conditions are met very completely by a sinusoidal current of very low *frequency*.

In a *paper* on this subject which it was my privilege to read before the Electro-Therapeutical Section of the annual meeting of *the British Medical* Association at Exeter last July, I then referred to what I called, for the want of a better term, the "*periodic time*" of a muscle; and by this I mean the length of *time any* given muscle requires in passing through the various *phases which follow* the application of an electrical impulse. These phases are, (*a*) the latent period; (*b*) the *period of contraction*; and (*c*) the period of relaxation; the sum of the three constituting what I have termed the "periodic time" of the muscle. I feel sure that this is a matter that will become increasingly important in the future both as regards diagnosis and *treatment*. Its practical application here lies in the fact that it gives us a clue as to the proper frequency to be employed in any given case. The time interval between the cycles of the current should *not exceed the* "periodic time" of the muscle. While it is not possible to determine the "periodic time" of the muscular coat of our patient's intestine by actual experiment, it is found as a matter of practical experience with degeneration in a superficial voluntary muscle that it is only in the more severe cases that the muscle makes no attempt to keep time with a current having a frequency of one cycle per second, and this frequency I may say is very *suitable for* the great majority of cases. I have been frequently asked if a three-phase current is necessary or has any advantages over a single-phase current. So long as the frequency is sufficiently low it matters little which is used.

The method of application is practically the same for all cases. I use three electrodes—one on each side of the lumbar spine and the third on the anterior abdominal wall—the epigastrium if the stomach is the part *chiefly at fault*, or over the course of the colon if the case is one of constipation, commencing at the cæcum and working gradually around in a clockwise direction. If the rectum is at fault a rectal electrode must be used, but not a bare metal one. It must be covered with membrane and water-jacketed so to speak. A certain amount of electrolytic products are set free owing to the rapid diffusion of the current and these become objectionable when bare metal is placed in contact with living tissues. If a single-phase current is being used the two posterior electrodes are joined to the same terminal. With a three-phase current the three electrodes are attached one to each of the three terminals of the apparatus. The duration of the applications is at first from 10 to 15 minutes, and the current just enough to cause gentle contraction of the abdominal muscles. The length of the application and the strength of the current are both increased on subsequent occasions, so that by the fourth or fifth the duration is 30 minutes and the current strength sufficient to cause strong contractions of the muscles of the anterior abdominal wall. This must be continued three times a week for a month or six weeks or more.

I will not take up your time by relating the details of the several cases which I have treated. There is a great sameness among them all, and I can only say that in all those in which the treatment has been regularly attended to for a sufficient time great improvement has taken place in the general health and in the local condition, so much so that the patients have in most cases voluntarily assured me that it had been well worth the time and trouble which it had entailed.

The great difficulty is to get the patients to come regularly for a sufficiently long time. Very often patients are only too ready to throw it up for some trivial excuse. This and the length of time required are the chief drawbacks to the method. But as regards time I ask, What other method can do better?

Before closing I should like to say something about the best means of generating the current I am advocating. Personally I use a large motor-dynamo which has collecting rings connected by the commutator on the motor side and allows one to take off a three-phase alternating current, and the armature is made to revolve slowly by means of a resistance in series, the field magnets being maintained at full magnetism. A large machine is preferable to a small one, however the latter may be arranged. The larger one is not so easily disturbed by small fluctuations in the current supplied to, or taken from, its armature, while its weight, bearings, and friction of brushes *provide* a *light but steady* mechanical load which is a great advantage. Machines of small size and made to run slowly by means of a *friction brake* have been in use but have not proved satisfactory in practice owing to their tending to rotate unevenly. Mr. Schall *has* got out a motor of comparatively small size, arranged with collecting rings and supplies the primaries of three sledge *coils. The* patient is put in circuit with the secondaries of these sledge coils. With my large machine I use the same method of regulation as it seems to be the best; the regulation is very fine and the patient is effectually cut off from the main current so that there is no danger of his getting shocks through touching anything connected to earth.

While this paper has for its main object the treatment of atonic conditions of the digestive system I would like to point out before I finish that this slow sinusoidal current will be found invaluable in the treatment of every condition where atony or degeneration of muscular tissue is the chief factor. Furthermore, having at hand an alternating or pulsating current of a frequency which is variable from one cycle in two seconds to, say, ten per second; and a means of ascertaining the frequency at any given moment I foresee a method of expressing the degrees of degeneration in muscular tissue in a numerical form, and according to the highest number of impulses per second or per minute to which the muscle will rhythmically respond we shall be able to have a better idea of the degree of degeneration existing in different cases and the progress of any given case by taking its highest frequency number from time to time. I hope to have something to say on this point at a future date.

Queen Anne-street, W.

NOTE ON

TWO CASES OF CHRONIC DYSENTERY TREATED WITH FORSTER'S ANTI-DYSENTERIC VACCINE.

BY E. A. R. NEWMAN, M.D. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,

MAJOR, INDIAN MEDICAL SERVICE; CIVIL SURGEON, RANCHI, INDIA.

THE following notes will, I think, be of interest to readers of THE LANCET. I was induced to give the method (vaccine-therapy) a trial after a perusal of a paper by Captain W. H. C. Forster, I.M.S.,[1] who kindly supplied me with vaccine and directions for use.

CASE 1.—The patient was a European woman, aged 28 years. She had resided for 11 years in India and had suffered from four acute attacks of dysentery during the first five years of that period. For 10 months she had been laid up with chronic dysentery, recurring subacute attacks alternating with short periods of constipation, and the evacuation of inspissated mucus with the stools. During this period she had been totally incapacitated, unable to walk, and only allowed out in a rickshaw. Subsequent improvement was followed by another acute attack within a year, which was succeeded by further manifestations for five or six months, until she went home to Scotland in April, 1905, about eight and a half years after coming out to India. For six months, while living in the North of Scotland, she had been quite free from any dysenteric symptoms. On her return to India at the end of 1905 she had had a sudden and very severe attack of acute dysentery which nearly proved fatal. Since then she had practically continuously suffered from looseness of the bowels with mucus contantly present in the stools. The patient came under my observation in April, 1906. By dint of a most careful diet and by leading a very quiet life she managed to get along with occasional relapses lasting for a few days. The least over-exertion, indiscretion of diet, or exposure to damp brought on mucoid diarrhœa with aching pain in the left side. During the rains of the year 1906 she showed some symptoms of sprue, which cleared up in time to prevent the necessity of going home as advised. She was treated from time to time with salines, castor-oil emulsion, bismuth, bael in season, and liquor hydrargyri perchloridi, the last-named drug seeming to be rather more useful than anything. The first injection was made into the left flank on July 30th, 1907. The evening temperature on that date was 99° F. and there was some neuralgic headache. She felt exactly as if an attack of dysentery were coming on (the patient volunteered this statement). Locally, considerable pain was felt in the site of injection, radiating round the waist and down into the left groin. In from 24 to 36 hours this subsided, leaving only a little local tenderness at the site of puncture. In three days' time the patient felt decidedly better and the looseness of the bowels had ceased. The second injection was made into the right flank on August 13th. There was slight pain for two or three hours only. The patient got wet through to the skin on the same evening when the temperature was 99°. Neuralgic headache and general aches and pains were present. Looseness of the bowels persisted for seven days and then the patient felt much better, the motions becoming formed once more. No treatment beyond the injection was employed. The third and last injection was made into the left flank on Sept. 3rd. There was slight discomfort at the site of puncture only. The bowels were loose for two days. Steady improvement now commenced, all traces of mucus disappearing from the stools, constipation temporarily replacing the daily or bidiurnal soft motion. Within two months the patient was enjoying such a feeling of health and *bienêtre* as she had not experienced for years. The appetite was good and she could eat anything in reason—potatoes, for instance, which formerly would have brought on diarrhœa at once. The patient's weight six weeks after the last injection was 8½ stones, the highest ever reached. The weight had not been taken before the treatment was begun, but certainly at least a stone had been gained and probably more. The patient has since maintained good health and can undertake exertion which previously was impossible without ill effects. A concrete instance of this is that she recently attended a dance till 4 A.M. without suffering in consequence.

CASE 2.—The patient, a native girl, aged 18 years, was admitted to hospital in September, 1907, with a history of chronic looseness of the bowels and mucoid stools, occasionally mixed with blood, for a period of one year. On admission she was anæmic and debilitated, with œdema of the feet and ankles. The symptoms persisted in spite of treatment and a milk diet. The first injection was made on Sept. 29th, about two weeks after admission. The evening temperature was 102° F. and there was little local discomfort. Rapid improvement in bowel symptoms followed. The motions became formed in a few days and blood and mucus disappeared from the stools. The second injection was made in two weeks' time. The constitutional and local discomfort were trifling. Improvement was maintained though the general health was still poor for about a month, when a slight relapse was experienced which probably was induced by eating uncooked vegetables. A third injection was made with satisfactory results. The patient had no return of dysenteric symptoms before she left the hospital at her own request some five weeks after the last injection.

Case 2 was typical of the condition of many patients who come for treatment, improve temporarily with rest and a suitable diet, &c., and relapse on discharge. This patient may be regarded as being in a fair way to permanent recovery, though the claim to a permanent cure would not be warranted by the limited time during which she was kept under observation.

Case 1 is as typical an instance of chronic relapsing dysentery as is likely to be met with. The recurring acute attacks finally lapsing into a pronounced condition of chronic infection, temporary improvement with another acute attack, followed by a further period of diarrhœa, apparent cure while living in a cold climate, to be again succeeded by another acute attack and all the old train of symptoms on returning to India, all point to an infection which was usually active and occasionally dormant for a period of between ten and 11 years. The results of vaccine-therapy in this case seem little short of phenomenal; in three months from the date of the first injection the patient was a different being. The actual discomfort after injection varies somewhat, possibly, I think, with the strain of vaccine used, and subsequent injections certainly seem from these and other instances in which I have had experience of it to be less painful than the first one. The occurrence of diarrhœa persisting for seven days after the second injection appears not unlikely to have been due to exposure to wet and cold during the temporary negative phase of opsonic power which would follow on the injection made a few hours previously, according to the teaching of Sir A. E. Wright.

I am induced to publish this note as I feel convinced from the experience of this case alone that we have in vaccine-therapy with Forster's anti-dysenteric vaccine a remedy which in suitable cases may be of the utmost value in combating an extraordinarily troublesome and obstinate complaint, responsible for no end of ill-health and possibly permanent invalidism amongst Anglo-Indians. I look forward to the day—I hope now not far distant—when the vaccine will be available for use by all practitioners, in India at all events. I believe that it will take the same place in practical therapeutics of dysentery that anti-diphtheritic serum now (though based on entirely different principles) occupies in the treatment of diphtheria. If this view is not Utopian—and I do not think it so—it will be impossible to estimate the importance to the State in reducing invalidism from dysentery and to the community at large in the prevention of suffering from this disease as a direct result of Captain Forster's labours and researches.

NOTE ON A CASE OF FUNCTIONAL PARAPLEGIA WITH ASSOCIATED PARALYSIS OF THE BLADDER.

BY ÆNEAS ROSE, M.A., M.B., CH.B. EDIN.,
LATE HOUSE PHYSICIAN, NORTH-EASTERN HOSPITAL FOR CHILDREN, LONDON.

THE patient, a female, aged 22 years, a domestic servant in the household of a medical man, was admitted into the Grantown-on Spey Cottage Hospital on August 14th, 1907, with a history of violent hysterical attacks occurring at frequent intervals for several weeks previously, retention of urine for two days, and complete inability to walk. She had previously been treated privately by Dr. W. H. M. Barclay, medical superintendent of the hospital, but owing to the difficulty of obtaining complete isolation she was removed to a private ward in the hospital.

On admission the patient was in a highly excited condition, paraplegic, and unable to pass her urine. There was considerable cyanosis of the lips and cheeks, a systolic murmur was heard over the heart, the extremities were cold, and there was complete absence of sensation over the whole of the lower limbs. The excitement was soon followed by a period of depression during which she seemed to be completely unconscious of her surroundings. She suffered extreme nausea at the mere sight of food and shortly after admission she vomited a quantity of blood. Her temperature, taken in the axilla on the night of admission, stood at 112° F. The menstrual function before admission had been fairly regular. As regards her former health, she had been twice before in hospital, for 15 weeks during the spring and summer of 1906 and for 11 weeks in the spring of 1907. On each occasion she had suffered from mild hysterical attacks which rapidly subsided with rest in bed, milk diet, and occasional doses of sulphonal and trional. She had suffered no other illness and her family history was excellent.

During the patient's first week in hospital her temperature ranged between 104° and 110° and for the next six days between 99° and 104°. She was never detected malingering, although Dr. Norman Moore, who was visiting the district at the time and was asked by Dr. Barclay to see the case, drew attention to the possible origin of the hyperpyrexia. After the first fortnight the temperature remained subnormal but on Nov. 1st, 11 weeks after admission, she was still *in statu quo* as far as her other symptoms were concerned. The attacks of excitement and crying, with the subsequent fits of depression and unconsciousness, had rapidly subsided, the heart sounds soon became normal, and the cyanosis of the lips and cheeks completely disappeared, but the paraplegia with the associated bladder symptoms remained unchanged. Rest and isolation, with milk diet, the bromides, valerianates, asafœtida, massage, and electricity were all tried in vain.

When seen on Nov. 1st the patient's condition was as follows. Height, 5 feet 2 inches; weight, 6 stones 13 pounds; general nutrition, fair; complexion, "pink and white"; no anæmia; no cyanosis; bowels fairly regular; appetite very poor; complete paraplegia with paralysis of the bladder. She had been catheterised twice daily since admission, and her condition in this respect seemed hopeless. The condition of the lower limbs, in spite of regular massage and careful faradic stimulation daily, seemed equally hopeless. The anæsthetic areas extended upwards on each side to a point slightly above the knee-joint. Over this area the anæsthesia to pain, heat, and cold was complete. On the outer side of the limb it extended almost as high as the buttock; on the inner side it stopped short just above the knee. The upper limbs were normal with this exception, that the hands, and especially the finger-tips, were curiously insensitive to pain. The knee-jerk was exaggerated on both sides; there were a slight tendo Achillis response, no ankle clonus, and no plantar reflex.

The urine was repeatedly examined but no abnormal constituents were found. Unfortunately no blood count was taken during the period of cyanosis. In other respects the patient was quite comfortable. On palpation there was some pain over the left iliac fossa and on deep pressure in that region the pain was acute and caused intense flushing and perspiration over the face and neck. Latterly she had been allowed an occasional visit from her friends.

It was now decided to take advantage of the method of treatment introduced by Cathelin for dealing with obstinate cases of functional enuresis, a method practised with success by Dr. George Carpenter at the North-Eastern Hospital for Children. Four drachms of normal saline solution were introduced into the epidural space of the spinal cord, the needle being inserted at the level of the cornua of the sacrum so that the injection should reach the nerve roots of the cauda equina. This was done on Nov. 5th, and the patient complained of great nausea but little pain during the injection. The only immediate result, apparently, was that the patient rejected every meal for several days afterwards, frequently vomiting blood with the rejected milk. Rectal feeding was resorted to for four days. There was no improvement in the bladder symptoms. A second injection was made on Nov. 19th. The patient complained of great pain and sickness during the injection, but that night she made a voluntary though futile effort to dispense with the catheter. On the next day she was transferred to a different private ward and handed over to Miss Rae, the matron, with instructions that her isolation should be absolute. She was put on a purely milk diet, from four to six pints daily. She was not allowed to knit or read and any convenient basins for holding vomited matter were kept out of reach. The catheter was to be avoided as far as possible. The patient's temperature that night went up to 105°, but when taken by the matron shortly afterwards it was still subnormal. She made several unsuccessful attempts to pass urine, but catheterisation was necessary on the two days following her removal. On Nov. 23rd, however, she succeeded, for the first time since her admission to hospital on August 14th, in passing urine without the aid of the catheter, and from that time onwards she never required it again. Two days later she said that she had some feeling in her legs and on the next day she could move them slightly. By Dec. 1st the patient was able to move out of bed and to stand on the floor with the matron's assistance. A week later she could walk round her room and dress herself without assistance. She was, in fact, quite well again. Her weight on Nov. 1st was 6 stones 13 pounds; on the 22nd it had gone down to 6 stones 9¼ pounds. From that time onwards she gained weight steadily and on Dec. 29th it was 7 stones 6½ pounds. By that time the patient was in excellent health and spirits and she found congenial occupation in helping the matron and nurses in the various lighter duties of the hospital.

This case resembled in some respects the cases of functional paraplegia that are met with in childhood. The true convulsive seizures met with in the graver adult types of the disease were absent. Beyond the pain felt on pressure over the left iliac fossa there was no reaction at any time to pressure upon the various hysterogenetic spots. The interest of the treatment by epidural injections lies in the fact that they were followed by a very rapid and complete recovery. One doubts whether the same result might not have been obtained by the mere removal of the patient to a quieter room, associated as that was with a very rigorous application of the Weir Mitchell treatment. One must admit the possible effect of such a powerful psychical stimulus as the introduction into the epidural space of a strong three-inch needle without even a local anæsthetic. Whether over and above this there was any real physical stimulation of the nerve roots of the cauda equina followed by a rapid improvement in the muscular tone of the bladder wall is necessarily a matter for conjecture.

I have to thank Dr. Barclay for his kind permission to use the notes of this case.

Grantown-on-Spey, N.B.

THE WEST AFRICAN MEDICAL STAFF.—Dr. M. Cameron Blair, senior medical officer in Southern Nigeria, has been transferred to Northern Nigeria, vice Dr. C. R. Chichester, from March 28th. Dr. C. R. Chichester, senior medical officer in Northern Nigeria, has been transferred to Southern Nigeria, vice Dr. M. Cameron Blair, from March 28th. Mr. J. B. H. Dawson, medical officer in Sierra Leone, has been promoted senior medical officer, vice Dr. D. H. R. Waldron retired, and transferred to the Gold Coast, from April 15th. The following gentlemen have been appointed to the staff since January: Mr. A. E. Oakeley (Northern Nigeria), Feb. 29th; Dr. R. P. Cockin (Southern Nigeria), April 25th; Dr. J. H. McKay (Southern Nigeria), April 25th; Mr. H. R. Morehead (Southern Nigeria), April 25th; and Mr. J. S. Pearson (Sierra Leone), April 25th.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Arterio-venous Anastomosis for Senile Gangrene.—A Case of Leucoderma; Death with Symptoms of Addison's Disease.—Rupture of Brachial Plexus.—Exhibition of Cases.

A MEETING of this section was held on May 8th, Sir THOMAS BARLOW, the President, being in the chair.

Mr. CHARLES A. BALLANCE read a paper on a case of Arterio-venous Anastomosis for Senile Gangrene. The patient was a woman, aged 75 years, who was admitted to St. Thomas's Hospital on Sept. 20th, 1907, with arterial gangrene of the first, second, and third toes of the right foot. The condition remained stationary for three weeks but she suffered so much pain that sedatives were required. At the end of three weeks the gangrene began to extend, all the toes became affected, and the discolouration of the skin extended over the dorsum of the foot. On Oct. 17th, an arterio-venous anastomosis was made in the upper half of Hunter's canal. The same evening an arterial pulse could be felt in the internal saphena vein and in the veins on the dorsum of the foot. The foot became warm and the pain was relieved. The discolouration of the skin of the fourth and fifth toes and of the dorsum of the foot disappeared. During the next few months the superficial gangrenous patches on the first, second, and third toes began to separate. The patient died from gangrene of the large intestine on Feb. 15th, 1908. Commenting on the questions raised by the case Mr. Ballance observed that it was now known that wounds of the heart and of the arteries and veins might be sutured; that a thrombosis or embolus might be removed by incision of the arterial wall; that portions of arteries and veins might be transplanted; that a portion of vein might be inserted between the cut and separated ends of a divided artery and that this portion of vein had a strong tendency to reconstitute the artery, assuming the anatomical characters and performing the function of an artery; that the venous system of a limb might be made to carry red blood when the arterial system is obstructed; that an anastomosis might be made between the portal and systemic veins; that varicose veins of the leg might be treated by anastomosis of the saphena vein with the femoral vein in the middle of the thigh, so that the blood to the saphena entered the femoral below the valves; that organs such as the kidney and ovary might be transplanted; and that in certain cases an aneurysm might not only be cured but gangrene might be prevented or arrested by arterio-venous anastomosis, not by occlusion but by reconstitution of the artery from which it arises, or the blood stream might be diverted from the aneurysm, as had been done in 1906 by José Goyannes. The result of the case narrated above would appear to justify the hope that a method was in sight which would replace in certain cases the necessity for amputation in senile gangrene and which might be applied to the relief of those distressing cases of endarteritis obliterans in the limbs of young people which are sometimes observed.—Dr. F. W. FORBES-ROSS described a method of operation by means of which advantage was taken of the vaso-motor dilatation following ligature of a main artery at various points and Mr. BALLANCE replied.

Dr. NORMAN DALTON read a paper on a case of Leucoderma in which the patient died with symptoms of Addison's Disease and in which Cirrhosis of the Suprarenals was found. The patient was an unmarried woman, aged 35 years at the time of death. She had had typical and widely distributed leucoderma for ten years and her health had been quite good all this time. The only noteworthy point about the skin affection was that the white patches had the faintest shade of pink in them, so that she was brown and pale pink, rather than brown and white. After death, however, the patches were quite white. In July, 1907, epigastric pain and vomiting set in. She became very weak and was admitted into King's College Hospital on Oct. 4th. On examination there, no indications of structural disease in any organ could be discovered. The vomiting continued and she became weaker. On Oct. 15th she became deadly faint and died in a few hours from cardiac failure. It was this final syncope, in conjunction with the vomiting, which suggested that Addison's disease was present, although the skin was typically leucodermic, and at the necropsy the suprarenals appeared simply to be atrophied. On microscopical examination, however, they proved to be cirrhotic. Dr. Dalton did not think that the association of the symptoms of Addison's disease with leucoderma was a mere coincidence, though he could offer no explanation as to why the innocent pigmentary changes, which were so unlike those of Addison's disease, should in any way be connected with the changes in the suprarenals and the gastric and cardiac symptoms. It was important, however, to recognise that if those symptoms supervened in a case of leucoderma some lesion of the suprarenals was probably present and that the prognosis was correspondingly grave. This case, though rare, was not unique, for McCall Anderson had recorded one of the same kind. Dr. Dalton did not discuss the pathology of leucoderma, but stated that the case might be heard of at a future time in that connexion, for Mr. G. Lenthal Cheatle had found pathological changes in the Gasserian ganglion corresponding to the white patches on the face.—The PRESIDENT referred to the case of Addison's disease with peculiar pigmentation, described by Dr. D. J. Leach in the Transactions of the Pathological Society of London, Vol. XXX., p. 478.—Sir DYCE DUCKWORTH said that the condition of the suprarenals in Dr. Dalton's case was different from that commonly found in Addison's disease.—In reply to Dr. F. PARKES WEBER, Dr. DALTON said that he was unable to say whether the white areas began as white patches on normal skin, because the condition commenced ten years ago when the patient was not under his observation.

Dr. G. F. STILL showed a girl, aged nine years, from whose stomach a hair ball had been removed. He said that the patient was admitted into King's College Hospital on Feb. 12th on account of an abdominal tumour which had been noticed first seven months previously. The abdomen had been noticed to be large for about a year, and there had been frequent sickness almost daily for several months; the child had become more ill during the last two months. The appetite was very bad, the bowels were regular; for the last three weeks the child had taken milk only. There had been much "pain in the pit of the stomach" for three months. The mother stated that for several years past the child's hair dropped out during two days in June. (No importance was attached to this statement, nor, indeed, to the scantiness of the child's hair, until operation showed the nature of the tumour, when it was ascertained that the child had been in the habit of pulling out her hair and eating it since she was three years old.) On admission the child was bright and intelligent, somewhat wasted and pale, but not acutely ill. There was no sign of disease except in the abdomen which was large and lax and showed as the child lay on her back a slight prominence across the epigastric region, which on palpation corresponded to a very hard tumour extending from the left costal margin in the splenic region to the right nipple line, where its lower edge was at the level of the umbilicus; it was two and three-quarter inches wide at its thickest part which was near its right extremity. Its upper and lower edges and its right extremity were well defined and seemed quite superficial, though evidently inside the abdominal cavity; it was not tender; its surface was smooth; it was thought to be slightly moveable up and down. Various diagnoses were suggested, including enlarged spleen (but the spleen seemed to be definable by percussion and not continuous with the tumour) and lymphosarcoma, and a tuberculous infiltration. Whilst in hospital the child seemed free from pain and vomiting was only occasional, but the child would take very little food. It was decided to explore and Mr. F. F. Burghard performed laparotomy. The stomach was found to be dilated by a hard mass which was evacuated through a longitudinal incision about three inches long near the pyloric end of the stomach. The mass proved to be a hair ball, weighing 17 ounces and measuring in its long axis 6 inches, in circumference 7¼ inches, and along its greater curvature 13¾ inches. It had exactly the shape of the stomach, of which indeed it formed a solid cast; it tailed off at the cardiac orifice into a narrower tail-like portion which must have extended quite two inches up the œsophagus.—Mr. BALLANCE described a similar case in which he found at operation that the mass did not extend into the œsophagus but passed into the jejunum.—After Dr. TRAVERS R. M. SMITH and Mr. T. S. TOWNSEND had spoken, Dr. STILL replied.

Mr. BALLANCE narrated the facts of a case of Rupture of the Upper Cord of the Brachial Plexus during Childbirth, treated by operation ten months afterwards. He said that the muscular reactions when examined under chloroform showed that the deltoid, biceps, brachialis anticus, coracobrachialis, and the supinator longus were totally paralysed. The plexus was exposed by operation in October, 1903. The fifth cervical nerve was found to have been ruptured just where it joins the sixth. The nerves were identified by stimulation. Reunion was effected by suture with silk 0000. Shortly afterwards the parents took the child to Hong-Kong. On their return with the child after four years' absence the paralysed muscles had completely recovered. At the present time, notwithstanding the strong action of the biceps, complete supination could be voluntarily effected. The pectoralis major was shortened and there was limited abduction; it was a question whether that tendon should be lengthened.—Dr. F. J. POYNTON said that the difficulty in such cases was to know when to advise and when not to advise operation. He had been surprised when following up these cases at the recovery seen in many without operation; though at first the lesion seemed exceedingly severe and the subsequent recovery was not quite complete, still it was of such a degree that it was doubtful if any operation would have produced as good a result.—In reply to Mr. C. H. FAGGE, Mr. BALLANCE said there was no time limit against operation: a good result could be expected from nerve union as long as muscular movement could be obtained by stimulation, even by strong stimulation under chloroform.

Mr. W. WATSON CHEYNE showed a case of Spontaneous Disappearance of Recurrent Carcinoma of the Breast. The patient was a female, aged 50 years, who was admitted to King's College Hospital on Sept. 26th, 1901, suffering from malignant disease of the right breast. She first noticed pain in the breast and swelling some eight months before admission; somewhat later retraction of the nipple was observed. On examination there was a large hard nodular lump in the right breast, about three inches in diameter, which was adherent to the skin and to the pectoral muscle. The nipple was retracted. The tumour was situated in the centre of the breast and its outline was indefinite; the skin was red over it but had not ulcerated. There were numerous large glands in the axilla and there were enlarged glands in the posterior triangle of the neck. On Oct. 2nd the usual extensive operation was performed, the glands in the axilla being thoroughly cleared out, as well as the fat and glands in the posterior triangle. It was quite impossible to close the wound and skin grafting was performed on Oct. 22nd. She left the hospital with the wound soundly healed on Nov. 5th. The tumour, on microscopical examination, was found to be a carcinoma. Early in 1903 she returned to the hospital with several small nodules in and under the skin, especially over the right side of the chest. There were also subcutaneous nodules in the upper part of the abdomen and elsewhere in the vicinity. These nodules were not examined microscopically, but there was not the slightest doubt that they were of a cancerous nature and represented a diffuse skin infection. Further local operation was evidently useless and oöphorectomy was suggested; that, however, she declined to submit to. On Oct. 1st, 1907, a letter from her stated: "About three years ago I found that all the lumps had disappeared, even those from the neck, soon after the menses ceased, since when I have got stronger and am altogether better in health. I have taken no medicine of any sort, lived just as before, only in place of drinking ale have used fresh lemons." On examination it was found that her statement was correct; there was no trace of the nodules which were present formerly or of any sign of recurrence of the disease.

Dr. PURVES STEWART showed a case of *Gross Lesion of the Post-central Gyrus associated with Astereognosis.* The patient was a man, aged 50 years, without history of syphilis. In 1894 or 1895 he began to complain of buzzing tinnitus in the right ear and occasional headaches, unilateral, but not always on the same side. In 1901 he had paroxysmal pains in the right hand and forearm for about three weeks. In 1904 the headaches became more severe, and in the end of 1905 he began to have attacks of vomiting. When first examined in 1906 he showed no evidence of aphasia or of weakness of any limb; the optic discs were normal. In August, 1907, he began to complain of occasional subjective sensations of tingling in the right index and middle finger and of difficulty in finding his words. He made mistakes in spelling and his memory became impaired. On examination in September there was weakness of the right lower face without weakness or ataxia of the limbs on either side. The optic discs and cranial nerves were normal. The deep reflexes were normal on both sides; the plantar reflexes could not be elicited. Speech was hesitating and in writing he made frequent mistakes of spelling, tending to miss out letters or to write the wrong letter. He could execute spoken or written commands. Shortly after this, in spite of energetic antisyphilitic treatment, the headache became more intense and was now localised to the left parietal region. The right upper limb became clumsy and slightly weak. He developed astereognosis, failing to recognise objects such as a watch-chain or a safety-pin with the right hand and succeeding with the left. The deep reflexes were normal on the two sides in the upper and lower limbs. By the middle of October speech had become still more impaired with difficulty in finding words and occasional jumbling of syllables. There was no hemianopia. The right lower face was weak and the right fingers and wrist were totally paralysed and flaccid, the elbow and shoulder being feeble. The right leg dragged slightly in walking. There was no cutaneous anæsthesia or analgesia; the supinator-jerk and knee-jerk were increased on the right side; the plantar reflexes were not elicited. The optic discs remained normal. The astereognosis of the right hand with the steadily progressive right hemiplegia and the intense headache, in spite of the absence of optic neuritis and vomiting, suggested a gross intracranial lesion in the region of the left post-central gyrus. The patient was accordingly sent to Mr. Ballance with a view to operation. On Oct. 28th Mr. Ballance performed the second stage of an exploratory operation in the left parietal region. The pia-arachnoid was thick and yellow over part of the left post-central gyrus, the patch of infiltration being strictly limited anteriorly by the fissure of Rolando. The diseased area occupied the post-central gyrus in its middle third and the adjacent part of its lower third. At a small distance anterior to the pre-central gyrus, over the middle frontal gyrus, there was a small stellate patch of opacity in the pia-arachnoid, not purulent as in the post-central gyrus. The diseased area of meninges and subjacent cortex in the post-central gyrus was removed. On Nov. 5th speech was hesitating, the patient talking in monosyllables or isolated words, not in sentences, and occasionally misplacing his syllables. He could read aloud but did not attempt to execute written commands. He could repeat sentences spoken to him and he understood and executed spoken commands. He could copy written sentences with his left hand but could not write spontaneously. No cutaneous anæsthesia or analgesia was present. Distinct atopognosis to touches existed in the right hand, the touches being misjudged in a proximal direction; with pin-pricks localisation was accurate. Joint-sense was normal in the right shoulder and elbow but was lost in the right wrist and fingers. Astereognosis of the right hand was as before. The external ocular movements were normal; the right lower face was weak, both on voluntary and emotional movement. The right shoulder and elbow were feebler than the left; the movements of the right wrist, especially extension, were still more feeble. The fingers were totally paralysed. There was some wasting of intrinsic hand muscles, especially the interossei in the right hand. The right lower limb was slightly feebler than the left and dragged a little in walking. The right supinator jerk was markedly increased and the right knee-jerk was moderately increased; there was no ankle clonus. Plantar reflexes were both flexor in type. On Nov. 22nd speech had begun to improve, though still "telegraphic" in style. He had been reading the sporting papers and remarked, "Cricket match," "Australia," "draw." He sang the airs of "God save the King" and "Auld Lang Syne" accurately but confused the words. He had no word-deafness. He could copy written words and write simple words to dictation. Atopognosis of the right hand was now practically gone. There was no cutaneous anæsthesia or analgesia. Joint-sense was normal at the shoulder and elbow, and was lost at the wrist and fingers. Astereognosis with objects placed in the right hand was present as before. There was now no absolute paralysis of any movement of the right upper limb, though all movements were feeble, especially in the fingers. The wasting of the intrinsic hand-muscles was distinct. The deep reflexes on the right side were increased, chiefly in the upper limb; the plantar reflexes remained flexor in type. At the present time the aphasia had largely cleared up and amounted merely to hesitation in speech with some slurring of articulation. There was moderate weakness of the right lower face and of the right upper limb at all joints. The right lower limb was practically normal. There were no sensory changes save in the right hand. He could feel and localise light touches and pin-pricks all over the hand, though there was occasional atopognosis. Heat and cold were appreciated normally. Joint-sense was normal in the shoulder, elbow, and wrist, but was impaired in all the fingers, the thumb being least affected in this respect. Astereognosis was as before. With the eyes shut he failed to recognise objects placed in the right hand, such as a bottle, a watch, a chain, a pencil, a penny, all of which he recognised promptly with the left hand. The deep jerks in the right upper limb were markedly increased and in the right lower limb only slightly increased; there was no ankle-clonus and the plantar reflexes were flexor in type.

Dr. J. BARNES BURT exhibited three cases of Gout showing Destructive Changes in Bone. The first was a patient, aged 67 years, who had suffered from gout on and off for the last 25 years. It began in the left ankle; practically every joint in the body had been affected at one time or another. The hands were first affected 21 years ago; "chalk" appeared 12 years ago. There were numerous tophi on both hands and around the toes, and a few small deposits in both ears. The synovial membranes of the knee and ankle joints were thickened and the patient had been unable to walk for the last 11 years. Both hands were much deformed by tophi; in several situations the skin had ulcerated. A skiagram of the left hand showed a "mashed-up" appearance of the carpus and ulnar deflection of the fingers. There was necrosis of bone of the size of a sixpenny-bit; in the proximal end of the first phalanx of the index finger the bone was expanded around the area. There was a similar but smaller area in the corresponding phalanx of the next finger; also several small punched-out areas of necrosis in the distal end of the second phalanx of the index finger. It was important to notice that there was no tophus over the metacarpo-phalangeal part of the index finger, the small hard lump felt there being part of the head of the second metacarpal bone; also the skin over the area was quite healthy. The second case was that of a female, aged 36 years, who had suffered from gout for the last five years. The first attack was in the right big toe. The hands were not affected till three years ago; most of the joints had been affected at some time or other. At the end of last year she was seen in an acute attack of gout. The toes, both knees, and the left wrist were affected. There was a uratic deposit in the right olecranon bursa, also around the terminal joint of the middle finger of the left hand. There was some limitation of movement in the right wrist. At the present time there were no abnormal physical signs in any other joints with the exception of the terminal joint of the middle finger of the left hand. There was a semi-soft slightly tender swelling round this joint; on the dorsum was a scar, the site of an incision made a year ago in one of the London hospitals, where it was mistaken for a whitlow. Crystals of sodium urate were obtained from the spot. The movement in that joint was only slightly impaired. A skiagram of the left hand showed a necrotic area of about the size of a pea in the distal end of the second phalanx of the middle finger. The third case was that of a man, aged 55 years, who had suffered from gout on and off for the last five years. In January last he was seen in an acute attack of gout, affecting first his feet and knees and later both hands, hips, and the neck. During the acute attack a blister appeared over the terminal interphalangeal joint of the index finger of the left hand. On puncture a milky fluid exuded which under the microscope was seen to be composed of crystals of sodium urate, together with a few leucocytes. At the present time there were no tophi to be seen. In the left hand a small bony nodule could be felt over the terminal joint of the index finger. Movement in that joint was only slightly impaired. There was slight hyper-extension of the proximal interphalangeal joint of the middle finger. Movement in this joint was free. The terminal joint of the little finger of the right hand was ankylosed. A skiagram of the left hand showed a light area in the distal end of the first phalanx of the middle finger; also another light area in the distal end of the second phalanx of the index finger. A small bony addition could be seen on the inner side of the first phalanx of the middle finger.—Sir DYCE DUCKWORTH considered that the theory of Ebstein that before uratic deposit occurred there must be a necrosed condition of the bone was incorrect. Many of these bony enlargements occurred quite apart from uratic deposit.—Dr. POYNTON believed that necrosis took place in the bone prior to the deposit of biurate of sodium. He thought that it would be interesting to investigate bacterial action in these cases.

Mr. HENRY CURTIS showed skiagrams of two cases of Congenital Absence of Both Thumbs and exhibited one of the patients with this somewhat rare deformity. Both cases had been seen by him at the Metropolitan Hospital, Kingsland-road, within the last four months. The case shown was a young man, aged 19 years; the other a girl, aged six months, was under treatment for scurvy rickets by Dr. W. Langdon Brown. This patient, whose deformity was indicated in the skiagram, showed no other malformation, but Dr. Langdon Brown made the interesting observation that another child in the family suffered from congenital heart disease. The skiagram showed the commoner variety of this deformity—namely, absence of the thumb and first metacarpal, associated with defective (or in some cases absent) radius. The patient shown to the society by Mr. Curtis was an example of the other and rarer type where the absence of the thumb and first metacarpal is unaccompanied by any defect in the radius, which skiagrams showed was as normal as the ulna. The trapezium and the scaphoid were also entirely absent; the trapezoid was present, but perhaps not quite normal in shape; all the other carpals and metacarpals and phalanges (with the exception of the middle phalanx of the little finger, which was shortened) appeared to be normal. The little finger on both sides was shorter than normal. There was some appearance of a thenar eminence, probably the result of constant practice in attempts to adduct the first digit (index finger) so as to grasp articles such as a knife or pen, which the patient could hold between the first and second digits. He could write his name fairly well, but he said he could not carry dishes and that owing to his deformed hands he was unable to follow any occupation. He was stunted in body and his facial aspect and general physiognomy, together with his apparent lack of initiative, suggested that his intelligence was also somewhat defective.

Mr. FAGGE showed a case in which, for Recurrent Sarcoma, parts of the Femoral Artery and Vein were Excised. The patient was a female, aged 50 years, who was admitted into Guy's Hospital in September, 1906, for a tumour on the inner side of the right thigh; it had been present for six weeks and had continued to grow in spite of treatment with iodide of potassium. It was situated below, and internal to, the saphenous opening, was from 3 to 4 inches in diameter, hard, well defined, not fixed to skin or bone, but was within muscles. By a long incision the tumour and the whole of the adductor brevis, which was spread out over it, were removed as it was thought to arise in that muscle. Microscopically it was a spindle-celled sarcoma with some myeloid cells which, in Mr. J. H. Targett's opinion, arose not in the muscle but from the intermuscular fascia. The first recurrence was removed in July, 1907, and the patient was re-admitted in December for a second recurrence, of the size of an apple, at the junction of the upper two-thirds and the lower third of the thigh; on operating the growth was found adherent to the femoral sheath within Hunter's canal and in close proximity to the femoral vessels. The artery and vein were therefore ligatured above and below, and the portions within Hunter's canal were removed. The circulation in the leg was quite restored on her discharge 18 days later. A third recurrence was removed on March 13th of this year.

Mr. FAGGE also showed a case of Aneurysm of the Common Femoral Artery for which he had performed excision of the aneurysm and common femoral vein. The patient was a man, aged 26 years, who was admitted into Guy's Hospital for a tumour of the size of an orange in the right Scarpa's triangle. Four years previously he had a blow in this position with a crowbar and a year ago he had rheumatic fever. He had noticed the lump for eight months; it had gradually increased and had been painful for three months. The right external iliac artery was enlarged and pressure over it did not entirely stop the pulsation in the tumour, which was "expansile"; the right posterior tibial pulse was delayed and small. There were no signs of syphilis or cardiac disease. On March 30th the right external iliac artery was exposed and trebly ligatured with No. 4 French catgut; the lowest ligature was placed about 1½ inches above Poupart's ligament, as below this the artery was dilated. Pulsation in the aneurysm was diminished but did not cease, so the deep epigastric was ligatured and the incision was continued downwards and the superficial femoral artery tied. The aneurysmal sac was dissected out, the anterior crural nerve being peeled off it externally, and behind the superficial femoral vein was separated from it to a point at which it joined the deep vein, where its wall became so thin that it was thought necessary to ligature both veins; the deep femoral artery was ligatured and the whole aneurysm then came away, the external iliac rupturing below the ligatures as it was pulled down. After the deep circumflex iliac vessels had been exposed and tied the common femoral vein was tied just below Poupart's ligament. There was slight superficial gangrene at the inner edge of the wound and a small blister formed on the heel. The leg and foot presented a mottled aspect for 48 hours, after which sensation and power of movement returned, but the pulse in the tibial vessels could not be felt a month after operation.

Dr. G. A. **SUTHERLAND** showed a case of Scleroderma in a boy, aged five and a half years. The patient had an attack of measles six weeks ago, from which he recovered, but three weeks ago his father noticed that the skin of the boy's face felt tense and hard. He also seemed unable to open his eyes fully. The characteristic induration of scleroderma affected the face, including the eyelids, the scalp, the neck, and the upper and lower extremities. The tongue was distinctly hard. The ears were quite free from any thickening and the skin over the trunk was only slightly affected. There was no leucoderma or pigmentation. The skin for the most part was dry and harsh. A scratch on the indurated parts produced a persistent white streak, while one on a healthy part produced a red streak. The boy's general condition and development were good.

Mr. **ALBERT CARLESS** showed a case of Multiple Symmetrical Lipomata in a man, aged 37 years, who came under observation for the condition in 1905. The trouble first showed itself on the left side of the face in 1903 as a small lump which used to vary in size; but subsequently other swellings appeared on the right side of the face and behind the left ear. He had been operated on twice before 1905. Photographs were shown representing his appearance in June, 1905. There were large tumours reaching from the zygoma downwards to the angle of the jaw and backwards behind the ear on either side; also a submental mass and one in the occipital region. The facial masses were removed by operation, and it was found that the growths were definitely limited, but burrowed deeply. Their removal was difficult in the extreme, as the main vessels in the neck were laid bare and there were many adhesions. In November, 1905, he was again operated on and the median submental mass removed. Here, too, the mass, though apparently diffuse, was in reality limited and well defined. This mass was easier of removal than the previous ones. The occipital mass was removed during his stay in hospital on this occasion. This, too, was definitely limited, though very adherent to surrounding parts; it had burrowed into and amongst the muscles at the back of the neck. At this time other growths were noted, one in the middle line over the isthmus of the thyroid, and one over each internal condyle in the arm. In February, 1908, he again came under observation when the main trouble was in the neck. The tumour in front of the thyroid isthmus had grown as large as a cocoanut and projected above the manubrium. It appeared to be well defined, did not move on deglutition, and caused no trouble in breathing or swallowing. It appeared to burrow deeply into the neck, and the veins over the chest wall were dilated, as if there were some mediastinal pressure. The mass was dissected away on Feb. 15th and had burrowed deeply and widely; prolongations passed backwards and downwards on each side, and finally disappeared along the vessels into the chest, where they could not be followed further. The side of the neck and the face had also been occupied once again with fatty masses, and there were symmetrical growths over the deltoids, over the spines of the scapulæ, and in the arms on either side. The points of importance in this case were that these growths, though sometimes termed diffuse lipomata, were in reality limited and localised, although the limits were sometimes difficult to define in the midst of the surrounding fat; that they tended to burrow and become adherent to surrounding parts; and that the burrowing might occur into regions such as the chest, where serious symptoms from pressure on important structures might result.

Mr. P. **MAYNARD HEATH** showed a case of Caries of the Spine with Clubbing of the Fingers and Toes. The patient was a girl, aged six and a half years, who had suffered from spinal caries for four years. The disease had apparently become arrested but with great deformity of the thorax. The clubbing of the fingers and toes had been noticed for 12 months. There was no evidence of abscess formation or of lung disease. The child suffered from occasional attacks of cyanosis. An x ray photograph showed very little change in the terminal phalanges.

Dr. **PARKES WEBER** showed a case of Multiple Idiopathic Hæmorrhagic Sarcoma of the Skin in a man, aged 52 years, who except for the present disease had enjoyed good health. The disease was said to have commenced about six years ago when he chanced to wound the sole of his right foot with a nail. A pedunculated growth arose from the wound which was removed by a medical man. Afterwards small, slightly elevated, hard, bluish or purple spots appeared in the skin of the lower extremities, especially the feet, and the left foot and ankle became swollen. From time to time sessile or pedunculated outgrowths, mostly not larger than a lentil or a pea, developed on the affected parts, chiefly on the left foot, and the little pendulous tumours tended to become ulcerated and to drop off or were knocked off accidentally. At present, except for a few minute raised purple or bluish spots on the hands and on the glans penis and neighbouring skin, the disease was confined to the lower extremities. It was most advanced in the left foot, over a great part of which the dark purple spots were confluent, and there was persistent œdema of the left foot and leg. Two or three characteristic little pendulous tumours on the left foot were "ripe" and quite ready to drop off. On the right foot there had for years been a large patch of brown pigmentation, the exact relation of which to the disease was uncertain. The lymphatic glands were not affected. The present case was a typical one of Kaposi's so-called "multiple idiopathic hæmorrhagic sarcoma," which J. Hutchinson had described as the "sarcoma melanodes of Hebra and Kaposi," and for which other terms had also been proposed, such as "granuloma multiplex hæmorrhagicum," "acroangioma hæmorrhagicum," and "acrosarcoma multiplex cutaneum telangiectodes" (Unna). A description of the present case was published three years ago.[1] Since then the disease had not progressed much. The patient had been away from London most of the time, and apparently no prolonged course of arsenic or atoxyl had yet been tried. There was no sign of any visceral disease.

THERAPEUTICAL SECTION.

Rheumatism and Chorea in Children.

A meeting of this section was held on April 28th, at the Apothecaries' Hall, Blackfriars, Dr. T. E. **BURTON BROWN**, the President, being in the chair.

Dr. **LEONARD G. GUTHRIE** read a paper upon Rheumatism and Chorea in Children. He maintained that salicylate of sodium and allied drugs were palliatives but not cures for rheumatism. Carditis and nodules appeared in patients fully under the influence of salicylates. The use of large doses of salicylates was not devoid of danger. It was contended that sodium bicarbonate was an antidote to the poison of salicylates, but to give poison and then antidote at the same time was a questionable therapeutic measure. The treatment of the acute stage of chorea was by rest in bed, quiet, isolation, protection from injury, and nourishing food. In severe cases hypnotics were necessary—chloral and bromide, chloralamide or chloretone. Arsenic, given on the intensive method, was not recommended. Ill results in the shape of gastro-enteritis and peripheral neuritis were too frequent. Salicylates, including aspirin, could not be regarded as curative. The average duration of chorea, under the mode of treatment recommended, did not exceed four or five weeks, and cases which did not recover under three months could not be considered testimonials to any form of treatment adopted.

Dr. R. **CECIL WALL** said that with almost all that Dr. Guthrie had said he felt himself in complete accord. Referring to statistics published in the Transactions of the Therapeutical Society for 1905, which he had compiled in an attempt to estimate the effect of different drugs in chorea, Dr. Wall stated that he then found that of cases treated by arsenic

---

[1] Parkes Weber and P. Daser in the British Journal of Dermatology, April, 1905, p. 135.

36 per cent. were cured in less than two months. Similar figures were given for treatment with salicylate of sodium and with other drugs. It was only when they came to the treatment with aceto-salicylic acid that they found a very marked difference. Of these 92 per cent. were discharged from hospital in less than two months, the majority in four weeks from admission. After two more years' experience of this treatment he still felt very strongly in favour of it. With regard to the dangers of the use of aspirin—the vomiting to which Dr. Guthrie had alluded—he found that it was possible to avoid that altogether if aspirin was only given when there was food in the stomach. Moreover, aspirin should never be given in compressed form but invariably as a powder. Very large doses, doses such as he himself would not prescribe, he had seen give rise to hæmaturia. In violent cases he thought it wise to make use of sedatives, and he would select chloral and chloralamide. He thought the use of bromides very harmful. In certain cases the result of giving bromides had been to produce mania. Any depressing drug like bromide was liable to exaggerate rather than to ameliorate the condition. He looked upon chorea as being due to a paralysis of the cortical centres, allowing the lower parts of the nervous system to act spontaneously.

Dr. D. B. LEES maintained that the neurotic element in chorea was largely the effect of the rheumatic toxin on the brain. He laid emphasis on the alteration in temper and disposition which was often manifested in children with early chorea. At times, too, there was very distinct aphasia, more than could be accounted for by simple weakness of muscular movement. Lastly, hallucinations of vision were not infrequently met with. In the treatment of rheumatism and chorea he advocated the use of very large doses of salicylate of sodium. He believed very strongly that salicylates were more readily tolerated if a double dose of sodium bicarbonate was given at the same time. When unpleasant symptoms occurred the dose should be decreased, not omitted; given in this way it was usually possible to educate the patient to tolerate without difficulty three or four times the dose which at first caused unpleasant symptoms. He had found such extraordinary benefit result from the local use of ice in pericarditis that he was surprised to hear Dr. Guthrie say that he gave opium in pericarditis because he did not know what else to do.

Dr. J. GORDON SHARP said that he had never found that depression resulted from the use of salicylates and he agreed with Dr. Lees that large doses did great good. He was much astonished that opinion in London was against the use of arsenic in chorea. His own experience in the North of England was that it was a most valuable drug. He thought that there must be something peculiar in the London constitution that could not stand that important drug. He believed very strongly that there was an intimate connexion between rheumatism and chorea.

Dr. J. GRAY DUNCANSON spoke of the success which attended the use of arsenic in chorea in Scotland. He thought that it was all a matter of environment.

OTOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on May 2nd, Dr. PETER MCBRIDE, the President, being in the chair.

Dr. W. S. SYME showed a case of Lateral Sinus Thrombosis in which recovery took place as a result of operation; also a case of Bezold's Mastoid Empyema which discharged into the pharynx.

Dr. J. DUNDAS GRANT showed two interesting cases of Unilateral Hysterical Nerve Deafness in conjunction with Dr. PURVES STEWART; also a case of Lateral Sinus Thrombosis following chronic suppuration of the middle ear in which ligature of the jugular vein was necessary.

Mr. P. MACLEOD YEARSLEY showed Specimens of Necrosis of the Labyrinth, the sequestra consisting of part of the vestibule, with the openings of the semicircular canal and of part of the promontory and cochlea. The patient, who was extremely ill before operation and suffered from vertigo and tinnitus, is now almost well again.

Dr. E. FURNISS POTTER showed a case of Chronic Eczema of the Auricle and Meatus on each side; the hyperplasia was so great that the lumen of the auditory canal was almost completely obstructed and the auricle was markedly thickened causing considerable deformity.

Mr. HUNTER F. TOD showed a case of Complete Atresia of the Posterior Nares, with flattening of the nose externally and almost complete absence of the nasal septum. The condition was due to congenital deformity or syphilis, probably the latter.

Dr. V. H. WYATT WINGRAVE demonstrated specimens, photographs, and diagrams illustrating his paper on the Clinical Pathology of Aural Discharges. In this interesting and instructive paper, the result of over five years' uninterrupted research work, Dr. Wingrave pointed out the importance of obtaining as much information as possible from the character of the discharge both from a bacteriological and cytological point of view. Such examination would be useful in determining whether the disease was acute or chronic or whether the deeper structures were involved or not; in addition, the character of the epithelium would show what part of the middle ear was affected and if of a cholesteatomatous nature. Further, a careful record of the bacteriological examination of a large series of cases in conjunction with the clinical symptoms might in the future considerably assist the surgeon in determining the question of operation and prognosis. Although cytology was still in its infancy Dr. Wingrave felt sure that it would soon be as justly appreciated as the examination of other discharges such as sputum, blood, urine, vomit, fæces, and cerebro-spinal fluid which were now so necessary to the clinician.

MEDICAL SOCIETY OF LONDON.

Recent Advances in the Surgical Knowledge and Treatment of Syphilis.

A MEETING of this society was held on May 11th, Dr. J. KINGSTON FOWLER, the President, being in the chair.

Mr. D'ARCY POWER read a paper on Recent Advances in the Surgical Knowledge and Treatment of Syphilis. He drew attention to the advantage of reviewing the knowledge of every scientific subject from time to time because advances in one branch often led to progress in others which appeared at first sight to be remote from it. The recognition and treatment of syphilis, he said, had occupied a disproportionately large amount of attention ever since the introduction of the disease into Europe at the end of the fifteenth century, partly on account of its manifest effects on the bodies of patients and partly because its advent was coincident with a very active period in the intellectual life of Europe which made men accurate observers and careful recorders of everything that was new to them. The diagnosis and treatment of syphilitic disease of the bones and joints had been greatly helped by progress in optics, leading to the production of better microscopes, by advances in physics resulting in the discovery of the Roentgen rays, and by the rapid progress of pathology, itself based on physics, chemistry, and biology, which had led to the discovery of the spirochæta pallida as the essential micro-organism causing the disease. Mr. Power then pointed out that histology enabled cases of tumor albus or white swelling of joints to be classified as tuberculous and gummatous. The distinction between these two forms was thought at first to be absolute and the text-books accordingly described the signs and symptoms of the two conditions as being entirely distinct. They failed to take any account of an intermediate form which was neither wholly tuberculous nor entirely gummatous but appeared to be a tuberculous infection of the joints occurring in those who had inherited syphilis. Reference was made to two cases of this nature, the one occurring in a boy, aged 14 years, and the other in a man, aged 38 years. Mr. Power thought himself justified in asserting that it was now necessary to form a series of intermediate groups due to the microbic infection of tissues the character of which had been modified by the action of the spirochæta pallida. Tubercle and syphilis formed, he said, the most frequent combination leading to chronic disease of the joints, but some varieties of pneumococcus and staphylococcus showed a special liability to invade syphilitic tissues, whilst an attack of influenza often proved the starting point of a gummatous arthritis in syphilitic patients. But in all this there was nothing very new, he said, for it had always been recognised that phagedænic inflammation was frequent in syphilitic patients, whilst the occurrence of cancer of the tongue in those who suffered from syphilitic leukoplakia was notorious. The Roentgen rays had enabled important advances to be made in the knowledge of syphilitic inflammations of bones and joints. The skiagraphic appearances of syphilitic osteitis and arthritis differed from those seen in the analogous inflammations caused by tubercle and rheumatism. The application of the x rays in cases of syphilitic bone disease had been particularly instructive, for it had enabled the effects of inherited syphilis to be traced onwards to a far more advanced period of life than had hitherto been thought possible. Mr. Power described the case of a man, aged 26 years, who had married young, whose wife was healthy and had borne him healthy children, and who had himself been free from any disease or ailment so long as he could remember. This man crushed his left arm between two vans. He continued to work for six months but it gradually became so swollen and painful that he applied for relief at St. Bartholomew's Hospital, saying that his elbow was getting stiff. A radiograph showed the appearances of a gummatous osteomyelitis of the lower part of the left humerus and the upper third of the bones of the forearm, whilst further examination revealed the existence of a puffy swelling over the centre of the left parietal bone and a gummatous ulcer on the right side of the neck. The patient was cured by a course of mercury preceded by a few doses of potassium iodide. Attention was further drawn to the interaction of tubercle and syphilis by the narration of a series of cases in which young persons presented the appearances characteristic of a leukoplakic tongue and had died afterwards from tuberculosis. The peculiar characters of a leukoplakic inflammation, it was contended, would not have been impressed upon the tongue in these patients if they had not inherited syphilis; indeed, in the absence of a syphilitic taint the tongue might entirely have escaped inflammation, for primary tuberculosis of the tongue was rare. Mr. Power thought that it would be extremely interesting to ascertain whether these children were the "healthy" offspring of parents who had been "cured" of syphilis before marriage or whether they had suffered in their infancy from other signs of inherited syphilis. Except for the leukoplakia they certainly presented no other evidence of syphilis and they were for the most part well-grown young women of pleasing aspect. The advances in the surgical treatment of syphilis had proceeded along two main lines. First, a thorough belief in the curative value of mercury when properly administered, the object of treatment being to cure the disease and not merely the symptoms complained of by the patient; secondly, a clear comprehension of the limitations of treatment by iodides. It was impossible for the tissues to rid themselves of large masses of inflammatory syphilitic products even with the help of iodides. It was better, therefore, to remove gummata, mucous patches, condylomata, and similar masses by ordinary surgical means rather than trust to their absorption by nature. Iodides might then be given with very satisfactory results, but they should always be followed by a mercurial course. Mr. Power concluded his paper by saying that his observations upon syphilis from a surgical standpoint brought him into line with those physicians who held that certain physiological factors would produce evidence of active syphilitic inflammation in those who had hitherto shown no trace of the disease though they were known to have inherited it. Mr. Power had endeavoured to show that injury might evoke a latent taint of inherited syphilis just as it had long been known to reawaken acquired syphilis.

The PRESIDENT observed that one of the points emphasised by Mr. Power was the possibility of the late appearance of inherited syphilis.

Mr. CAMPBELL WILLIAMS commented on the difficulties of diagnosing modified syphilis; and Colonel F. J. LAMBKIN, R.A.M.C., described how he had overcome the objections urged in Uganda against the use of mercury for the native and advocated intramuscular mercurial injections as the best way of treating syphilis.

Dr. STCLAIR THOMSON explained the advantages of tracheotomy in treating syphilis of the larynx.

Mr. C. J. SYMONDS raised the question whether late congenital syphilitic cases were not really cases of syphilis acquired in early life.

Mr. CHARLES RYALL dwelt on the importance of recognising the syphilitic origin of leukoplakia especially in reference to its relation with cancer. He also insisted on the value of rest in bed in an equable temperature in cases of syphilis.

Mr. C. F. MARSHALL spoke on the predisposition of the syphilitic condition to gonococcal infection and he was followed by Dr. H. F. WINSLOW and Dr. R. PARAMORE.

Dr. A. F. VOELCKER discussed the difficulty of diagnosing bone lesions in syphilis by x rays.

Major H. C. FRENCH, R.A.M.C., brought forward facts and figures in proof of the efficacy of the treatment of early syphilis by inunction.

Mr. POWER then replied.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 1st, Mr. Richard Lake, the President, being in the chair.—Dr. Herbert R. Spencer gave a short address on the Examination of the Pelvis and Abdomen during Pregnancy, its advantages and indeed its necessity if women were to have the full benefit of obstetric science at the time of labour. It was a practice which he had personally adopted during the last 20 years. Lantern slides were exhibited illustrating the advantages of the examination and the dangers and fatalities resulting from its omission. He advocated external and internal examination at the end of the third month and external examination at the end of the seventh month. Vaginal examination should be gentle; he warned especially against forcible bimanual examination and the eliciting of Hegar's sign as liable to produce abortion. The value of abdominal ballottement was referred to. Dr. Spencer stated that the height of the top of the pregnant uterus above the pubes was erroneously stated in English text-books At the end of the third calendar month it was as high as the promontory (three and three-quarter inches above the symphysis); at the end of the fifth calendar month it was on a level with the umbilicus. The height above the symphysis during the first six calendar months was obtained approximately by adding half an inch to the number of the month. It could be felt at two and a half inches above the symphysis in all ordinary cases at the end of the second month. The advantages to be derived from examination during pregnancy were that the fact and the period of gestation, the position of the uterus, and the presentation and position of the child were ascertained and treatment could be applied during the pregnancy. Presentation of the breech and shoulder would thus in many cases be prevented. Contraction of the pelvis could thus be discovered in time to decide on induction of labour or on Cæsarean section which in such cases should always be successful at the present day. —Dr. Seymour Taylor read a paper on Some Neglected Remedies. Commencing with external applications, Dr. Taylor advocated the use of the seton in some forms of congestive headache and even in epilepsy. He was convinced that in the latter disorder a judiciously applied seton deferred epileptic attacks and even rendered them less severe. Venesection again was valuable treatment in those diseases where the circulation through the right heart was embarrassed. He quoted three cases, one of chronic bronchitis and marked cyanosis and one of acute œdema of the lungs following mitral obstruction in which the patients were fully bled and both of them recovered when on the verge of death; the third case was one of suicidal hanging, and in this instance the external jugular vein was opened and life was prolonged to the third day. But bleeding should never be regarded as a routine practice as it was formerly. Bleeding was useful in many cases of pneumonia, for example, but chiefly when cyanosis was a marked symptom. The indications for bleeding were afforded by the heart rather than the lung. The blister was also a somewhat neglected remedy, yet it afforded great relief to the acutely inflamed rheumatic joint and the smart of a blister was more tolerable than the dull throbbing of a swollen joint. Blistering in pericarditis had been revived and with advantage. Consistency also demanded that if they blistered a rheumatic knee they should also blister a rheumatic heart; and they did so in many instances with the utmost benefit. Dr. Taylor then spoke of the use of some drugs. Sarsaparilla, an old-fashioned remedy, was undoubtedly a corrective remedy in some skin affections which were not syphilitic. But its chief efficacy lay as an adjunct to iodide of potassium in the treatment of cutaneous syphilides and of nodes. It should be prescribed in large doses. Other neglected remedies which were referred to were Plummer's pill in primary syphilis (this remedy should be freshly made); pulvis basilicus or royal powder as a febrifuge in children suffering from fever due to gastro-intestinal irritation; guaiacum, gum ammoniacum, and copaiba in chronic

36 per cent. were cured in less than two months. Similar figures were given for treatment with salicylate of sodium and with other drugs. It was only when they came to the treatment with aceto-salicylic acid that they found a very marked difference. Of these 92 per cent. were discharged from hospital in less than two months, the majority in four weeks from admission. After two more years' experience of this treatment he still felt very strongly in favour of it. With regard to the dangers of the use of aspirin—the vomiting to which Dr. Guthrie had alluded—he found that it was possible to avoid that altogether if aspirin was only given when there was food in the stomach. Moreover, aspirin should never be given in compressed form but invariably as a powder. Very large doses, doses such as he himself would not prescribe, he had seen give rise to hæmaturia. In violent cases he thought it wise to make use of sedatives, and he would select chloral and chloralamide. He thought the use of bromides very harmful. In certain cases the result of giving bromides had been to produce mania. Any depressing drug like bromide was liable to exaggerate rather than to ameliorate the condition. He looked upon chorea as being due to a paralysis of the cortical centres, allowing the lower parts of the nervous system to act spontaneously.

Dr. D. B. LEES maintained that the neurotic element in chorea was largely the effect of the rheumatic toxin on the brain. He laid emphasis on the alteration in temper and disposition which was often manifested in children with early chorea. At times, too, there was very distinct aphasia, more than could be accounted for by simple weakness of muscular movement. Lastly, hallucinations of vision were not infrequently met with. In the treatment of rheumatism and chorea he advocated the use of very large doses of salicylate of sodium. He believed very strongly that salicylates were more readily tolerated if a double dose of sodium bicarbonate was given at the same time. When unpleasant symptoms occurred the dose should be decreased, not omitted; given in this way it was usually possible to educate the patient to tolerate without difficulty three or four times the dose which at first caused unpleasant symptoms. He had found such extraordinary benefit result from the local use of ice in pericarditis that he was surprised to hear Dr. Guthrie say that he gave opium in pericarditis because he did not know what else to do.

Dr. J. GORDON SHARP said that he had never found that depression resulted from the use of salicylates and he agreed with Dr. Lees that large doses did great good. He was much astonished that opinion in London was against the use of arsenic in chorea. His own experience in the North of England was that it was a most valuable drug. He thought that there must be something peculiar in the London constitution that could not stand that important drug. He believed very strongly that there was an intimate connexion between rheumatism and chorea.

Dr. J. GRAY DUNCANSON spoke of the success which attended the use of arsenic in chorea in Scotland. He thought that it was all a matter of environment.

OTOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on May 2nd, Dr. PETER MCBRIDE, the President, being in the chair.

Dr. W. S. SYME showed a case of Lateral Sinus Thrombosis in which recovery took place as a result of operation; also a case of Bezold's Mastoid Empyema which discharged into the pharynx.

Dr. J. DUNDAS GRANT showed two interesting cases of Unilateral Hysterical Nerve Deafness in conjunction with Dr. PURVES STEWART; also a case of Lateral Sinus Thrombosis following chronic suppuration of the middle ear in which ligature of the jugular vein was necessary.

Mr. P. MACLEOD YEARSLEY showed Specimens of Necrosis of the Labyrinth, the sequestra consisting of part of the vestibule, with the openings of the semicircular canal and of part of the promontory and cochlea. The patient, who was extremely ill before operation and suffered from vertigo and tinnitus, is now almost well again.

Dr. E. FURNISS POTTER showed a case of Chronic Eczema of the Auricle and Meatus on each side; the hyperplasia was so great that the lumen of the auditory canal was almost completely obstructed and the auricle was markedly thickened causing considerable deformity.

Mr. HUNTER F. TOD showed a case of Complete Atresia of the Posterior Nares, with flattening of the nose externally and almost complete absence of the nasal septum. The condition was due to congenital deformity or syphilis, probably the latter.

Dr. V. H. WYATT WINGRAVE demonstrated specimens, photographs, and diagrams illustrating his paper on the Clinical Pathology of Aural Discharges. In this interesting and instructive paper, the result of over five years' uninterrupted research work, Dr. Wingrave pointed out the importance of obtaining as much information as possible from the character of the discharge both from a bacteriological and cytological point of view. Such examination would be useful in determining whether the disease was acute or chronic or whether the deeper structures were involved or not; in addition, the character of the epithelium would show what part of the middle ear was affected and if of a cholesteatomatous nature. Further, a careful record of the bacteriological examination of a large series of cases in conjunction with the clinical symptoms might in the future considerably assist the surgeon in determining the question of operation and prognosis. Although cytology was still in its infancy Dr. Wingrave felt sure that it would soon be as justly appreciated as the examination of other discharges such as sputum, blood, urine, vomit, fæces, and cerebro-spinal fluid which were now so necessary to the clinician.

MEDICAL SOCIETY OF LONDON.

Recent Advances in the Surgical Knowledge and Treatment of Syphilis.

A MEETING of this society was held on May 11th, Dr. J. KINGSTON FOWLER, the President, being in the chair.

Mr. D'ARCY POWER read a paper on Recent Advances in the Surgical Knowledge and Treatment of Syphilis. He drew attention to the advantage of reviewing the knowledge of every scientific subject from time to time because advances in one branch often led to progress in others which appeared at first sight to be remote from it. The recognition and treatment of syphilis, he said, had occupied a disproportionately large amount of attention ever since the introduction of the disease into Europe at the end of the fifteenth century, partly on account of its manifest effects on the bodies of patients and partly because its advent was coincident with a very active period in the intellectual life of Europe which made men accurate observers and careful recorders of everything that was new to them. The diagnosis and treatment of syphilitic disease of the bones and joints had been greatly helped by progress in optics, leading to the production of better microscopes, by advances in physics resulting in the discovery of the Roentgen rays, and by the rapid progress of pathology, itself based on physics, chemistry, and biology, which had led to the discovery of the spirochæta pallida as the essential micro-organism causing the disease. Mr. Power then pointed out that histology enabled cases of tumor albus or white swelling of joints to be classified as tuberculous and gummatous. The distinction between these two forms was thought at first to be absolute and the text-books accordingly described the signs and symptoms of the two conditions as being entirely distinct. They failed to take any account of an intermediate form which was neither wholly tuberculous nor entirely gummatous but appeared to be a tuberculous infection of the joints occurring in those who had inherited syphilis. Reference was made to two cases of this nature, the one occurring in a boy, aged 14 years, and the other in a man, aged 38 years. Mr. Power thought himself justified in asserting that it was now necessary to form a series of intermediate groups due to the microbic infection of tissues the character of which had been modified by the action of the spirochæta pallida. Tubercle and syphilis formed, he said, the most frequent combination leading to chronic disease of the joints, but some varieties of pneumococcus and staphylococcus showed a special liability to invade syphilitic tissues, whilst an attack of influenza often proved the starting point of a gummatous arthritis in syphilitic patients. But in all this there was nothing very new, he said, for it had always been recognised that phagedænic inflammation was frequent in syphilitic patients, whilst the occurrence of cancer of the tongue in those who suffered from syphilitic leukoplakia was notorious. The Roentgen rays had enabled peritonitis might occur from bursting of the abscess or extension from the underlying ulcer. The chronic form was usually diffuse and arose from spread of inflammation from neighbouring organs or the mucous lining of the bowel. The latter form where the inflammation infiltrated through and involved all the coats of the bowel generally occurred in the ascending colon or the iliac colon. The latter situation was most frequently affected and the disease had been known as perisigmoiditis or pericolitis sinistra. Of this form Dr. Lloyd Roberts had met with nine cases, four in men and five in women—six of the nine occurring between the ages of 21 and 26 years. He then described the clinical history and the physical signs and suggested that the cause lay in a late origin and narrowness of the mesentery of the pelvic colon, owing to which the bowel became kinked near the bony brim of the pelvis. The medical treatment consisted of administering intestinal antiseptics, external application of mercury and belladonna, and, most important of all, daily douching of the colon with hot antiseptic douches which should be persevered with for many weeks. Patients should be warned of the risk of recurrence should constipation again occur.—Dr. A. G. Gullan confirmed the statement that pericolitis sometimes resembled malignant disease and quoted a case in point.—Mr. Keith W. Monsarrat and Dr. W. Blair Bell also took part in the debate.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 1st, Dr. J. Walker Downie, the President, being in the chair.—Dr. James Adam read a paper on the Pathology and Treatment of Atrophic Rhinitis. Atrophic rhinitis, he said, was the end-stage of hyperplastic purulent rhinitis—i.e., of a septic process in which infiltration of round cells went on to fibrosis and in which there was already in the hyperplastic stage metaplasia of the epithelium. The following facts supported this view: the frequence of purulent hyperplastic rhinitis in the children of mothers suffering from atrophy and ozæna, the histological changes of atrophy in these cases and the same changes in the turbinals of cases of simple chronic sinusitis, and also the frequency (over 50 per cent.) of sinusitis in both stages of the disease. Sinusitis should be suspected in every case and negatived only after repeated careful examination. Sphenoidal sinusitis was very frequent with atrophic pharyngitis. Hypertrophic rhinitis was histologically quite distinct and did not go on to atrophy. Ozæna was merely an accidental symptom. Treatment by paraffin injection and by ionisation gave good results, but the best treatment was that of the hyperplastic stage in the young and the early treatment of sinusitis.—Mr. J. H. Pringle showed a patient on whom he had performed inter-ilio-abdominal amputation for sarcoma of the ischium under spinal analgesia by means of stovaine. The stump was now firmly healed and there was no hernia.—Dr. T. K. Monro and Dr. Leonard Findlay showed preparations from a case of General Tuberculosis with Diffuse Spinal Meningitis and Tuberculous Nodules in the Medulla and Cord. An extensive ascending degeneration had resulted from a nodule in the lumbar region and the meningitis. The nodule in the medulla had almost entirely destroyed the left olivary nucleus and had affected to a slight degree the pyramidal bundle on that side. The fact that the mischief was limited to the olivary nucleus and its immediate neighbourhood rendered the case eminently suitable for the study of the course of the much-debated cerebello-olivary fibres. These fibres were, excepting to a very slight degree, only degenerate in the immediate circumference of the nodule, so that it would appear that for the most part this bundle was descending in type.—Dr. Monro reported a case of Rheumatic Hyperpyrexia successfully treated by the cold bath.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held at Paddington Green Children's Hospital on May 7th, Mr. D'Arcy Power, the President, being in the chair.—The following clinical cases and specimens were shown and discussed:—Dr. Leonard G. Guthrie: (1) A case of Cerebral Diplegia in a child, aged four years, the onset of which was after an attack of measles at the age of two years. 2. A case of Cirrhosis of the Liver in a child, aged 10 years, with marked ascites; there was no evidence of congenital syphilis. 3. A case of Obliterating Endarteritis in a woman aged 42 years. The arteries of the right upper extremity were affected and no pulse could be felt. Pain and coldness of the affected limb were present and there had been troublesome whitlows. There was symmetrical malformation of the clavicles.—Dr. G. A. Sutherland: A case of Sclerodermia which had followed a recent attack of measles.—Dr. F. S. Langmead: (1) A series of cases of Congenital Malformation of the Nose ("Frog Nose") occurring in members of one family; (2) three cases of Mongolian Imbecility; and (3) a case of Tetany associated with Dilatation of the Large Intestine.—Mr. J. Keogh Murphy: (1) Cases of Tuberculosis of the Tarsus with skiagrams by Mr. A. D. Reid; (2) a case of Ischæmic Paralysis; and (3) a case of Vesical Calculus with skiagram.—Mr. Arthur Edmunds: (1) A case of Spina Bifida; (2) a case of Imperforate Anus which had been successfully operated upon; (3) a case of Hypospadias; (4) a case of Exostoses of Scapulæ and Ribs; and (5) Pathological Specimens.—Mr. M. S. Mayou: A case of Optic Neuritis in one eye due to retrobulbar inflammation.—Dr. G. de B. Turtle: Three cases with marked Eustace Smith's Murmurs. In one of the cases there were signs of enlarged tuberculous glands in the superior mediastinum with distension of veins over the upper part of the chest and characteristic cough.—Mr. E. Laming Evans: A case of "Fragilitas Ossium." There had been 12 fractures involving the right humerus and both femora. There was great deformity of the limbs and false joints had formed. Skiagrams were shown.—Dr. W. H. Willcox: A case of Congenital Dislocation of the Hip.—The cases were discussed by the President, Sir John Broadbent, Mr. E. M. Corner, Mr. Laming Evans, Dr. Guthrie, Dr. Sutherland, Dr. Langmead, Mr. Murphy, Mr. T. Crisp English, and Dr. Willcox.

Reviews and Notices of Books.

The Bacteriology of Diphtheria, including sections on the History, Epidemiology, and Pathology of the Disease, the Mortality caused by it, the Toxins and Antitoxins, and the Serum Disease. By F. LÖFFLER, M.D., LL.D., ARTHUR NEWSHOLME, M.D. Lond., F.R.C.P. Lond., F. B. MALLORY, M.A., M.D., G. S. GRAHAM-SMITH, M.A., M.D., D.P.H. Cantab., GEORGE DEAN, M.D. Aberd., WILLIAM H. PARK, M.D., and CHARLES F. BOLDUAN, M.D. Edited by G. H. F. NUTTALL, M.D., Ph.D., Sc.D., F.R.S., Quick Professor of Biology in the University of Cambridge, and G. S. GRAHAM-SMITH, M.A., M.D. Cantab., University Lecturer in Hygiene, Cambridge. Cambridge: University Press. 1908. Pp. 718. Price 25*s.*

THIS work marks a new departure in bacteriological literature. It is an attempt to present in one volume an account of the bacteriology of diphtheria complete up to the present date and it interprets the term bacteriology in so liberal a spirit that it includes the epidemiology and pathology of the disease and, indeed, almost everything except strictly clinical details and methods of treatment other than those based on bacteriology. The constant advance made in scientific research renders it a task difficult of accomplishment, but there can be no doubt as to the usefulness of the attempt, and the editors and authors of the work are to be congratulated on the success of their efforts. The appearance of this book has a further importance in that should it be successful it will be the first of a series of works having similar aims which will be published by the Cambridge University Press. The relations existing between the Universities of Oxford and Cambridge and their respective presses are rather elusive but a series of publications such as that proposed would seem to be one which a university press might well undertake and which would reflect credit upon it even if it should not prove to be a very profitable undertaking. The kind of completeness at which the editors have aimed is indicated in their preface when they hope that "the reader will seldom find it necessary to refer to the original papers" though a full bibliography forms part of the volume. While sympathising with this desire as indicating the thoroughness of the work, yet it can never be forgotten that there is an bronchitis with profuse or fœtid expectoration; galbanum and asafœtida for the relief of intestinal distension, so often a distressing symptom in failing heart; antimony in acute affections of the respiratory membranes; and lastly musk, which had apparently in two instances saved lives which in typhoid fever appeared to be on the brink of the grave.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 7th, Mr. H. H. Taylor, the President, being in the chair.—Dr. Walter Broadbent showed a man, aged 56 years, with Amnesia; he understood all that was said to him, but in talking only very rarely used a noun, and then accidentally rather than intentionally; he could not name anything at sight, but when the name was given said "Yes," and could repeat it; he could only rarely name a letter of the alphabet, often saying numerals instead; he could not read or understand print or writing, but could copy correctly print into writing, and write from dictation if the words did not exceed two syllables; he could play the piano without music, but if he tried to read music he could only play single notes, though he had formerly read music easily. The lesion was thought to be a hæmorrhage between the visual and the naming centres beneath the angular gyrus; there was no paralysis. He also showed a child, aged eight years, whom he admitted to hospital in January in a semi-comatose condition, with headache, vomiting, and double optic neuritis, and paralysis of the left sixth nerve and exaggerated knee-jerk and Babinski reflex on the right side. The child now appeared perfectly well, the external rectus moved well and the optic neuritis was subsiding; very large veins had developed in the middle of the forehead. The lesion was thought to be a tuberculous tumour in the wall of the left cavernous sinus. He also showed a boy who for four years had had enlarged glands in various parts and three months ago began to develop small scattered subcutaneous tumours, microscopically lympho-sarcomata.—Dr. C. F. Bailey showed a man with marked Locomotor Ataxy but with unequal pupils and tremor of the lips and tongue and hands; there were no delusions but the question arose whether general paralysis was supervening on ataxy.—Dr. R. Sanderson read notes and showed specimens from two cases of Malignant Disease of the Ovaries followed in less than six months by malignant disease of the uterus. In both cases he had removed both ovaries for cystic disease, discovered microscopically to be malignant; in the first case uterine symptoms had caused him to remove the uterus five months later, when advanced carcinoma was found. On the strength of this experience he had removed the uterus in the second case six months after the original operation, though the woman was fat and well except for a recent slight vaginal discharge, and carcinoma was discovered. He therefore advised immediate removal of the uterus as well as both ovaries when there was malignant disease of an ovary.—Dr. J. F. Gordon Dill read notes of an obscure case of Mastoid Disease resulting in Thrombosis of the Lateral Sinus and Suppurative Meningitis.—Dr. E. Hobhouse and Mr. Stephen Paget made some remarks advocating the formation of a local branch of the Research Defence Society. —Dr. C. H. Benham read an interesting paper on the Epidemic Catarrhal Fevers of 1907-08, illustrated by lantern slides. He found that the prevailing organism had been a micrococcus tetragenus, and that the bacillus septus of two years ago was less common; the micrococcus catarrhalis took a secondary place and the influenza bacillus was not found.—Dr. R. W. Allen gave an account of his work on the treatment of Colds by Bacterial Vaccines.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 1st, Dr. J. Allan being in the chair.—Dr. J. B. Hellier described the case of a woman, aged 42 years, who had suffered from symptoms of Osteomalacia for six years and whom he had delivered by craniotomy in 1906. The pelvis was contracted and rostrated with a true conjugate of about two and three-quarter inches. In June, 1907, he performed Cæsarean section with oöphorectomy and the relief to the symptoms of osteomalacia had been very decided. He discussed the etiology and distribution of the disease and the treatment by suprarenal extract and, if this failed, by oöphorectomy. In performing Cæsarean section he considered that it was not necessary in the interests of the mother to wait till labour began, but in the interests of the child it was better to do so. Otherwise there was considerable danger of terminating utero-gestation prematurely and so of delivering a child of less weight and vitality than would be secured by waiting till the full term which was notoriously difficult to calculate exactly. —Dr. E. F. Trevelyan read a paper on Epilepsy based on 100 more or less selected cases. Psychical epilepsy was met with alone in a woman, aged 51 years, and combined with minor attacks in a man, aged 39 years. In a female, aged 23 years, showing a mixed seizure type, somnambulism was observed. A case of otherwise unexplained narcolepsy in a boy, aged 14 years, was looked upon as probably epileptic. In an undoubted epileptic, aged 30 years, attacks of painful tonic spasm without loss of consciousness were observed. Serial epilepsy was seen in not a few cases. In a woman, aged 50 years, with apparently true Jacksonian epilepsy and aphasia no lesion was found after death. Among cases of so-called reflex epilepsy was a girl, aged 19 years, with almost innumerable minor attacks and marked astigmatism. Suitable spectacles produced some improvement but the ultimate result was still doubtful. Migraine and epilepsy were noted in two cases and a case of psychical megrim in a man, aged 30 years, with an epileptic father, was mentioned. Whenever possible the time of occurrence of the fit should regulate the treatment. Chronic epilepsy with at all frequent fits should be dealt with in epileptic colonies. Suitable treatment in genuine traumatic epilepsy and in so-called reflex epilepsy should be adopted before the epileptic habit became stereotyped.—Mr. R. Lawford Knaggs showed a specimen of Strangulated Prolapse of the Cæcum and Ileo-cæcal Valve through a typhlotomy opening.—Dr. J. H. Lamb showed a specimen of Ruptured Spleen without history of injury. The patient had been found in bed in a collapsed condition and died very soon. Microscopic examination showed nothing but fibrous capsulitis of the spleen.—Mr. H. Secker Walker exhibited two Eyes showing Panophthalmitis occurring in cases of pyæmia: (1) from a case of septic arthritis of the knee; and (2) from a crush of the hand; in this case both eyes were affected.—Dr. T. Churton and Mr. H. Littlewood showed a case of Extirpation of Aneurysm of the Left Common Carotid Artery.—Mr. A. L. Whitehead showed a patient in whom Tuberculous Keratitis had been treated by injections of tuberculin with emulsion of bacilli. A vascular growth appeared in the lower part of the cornea in September last and steadily increased in size with the formation of some outlying nodules in spite of all treatment, local and general, with open-air life. A month ago tuberculin injections were commenced, the opsonic index being 0·68; reaction followed the first injection but not the subsequent ones. The growth in the cornea rapidly diminished in size after the first injection and has now almost disappeared, leaving only a cicatrix. —Dr. W. H. Maxwell Telling and Mr. Littlewood showed a case in which partial hepatectomy had been performed for an Actinomycotic Nodule in the Liver adherent to the Omentum. At the operation other nodules were noted in the liver. The patient appeared to be doing well on iodide of potassium, of which she had been having six drachms daily for many weeks without the slightest discomfort.—Cases and specimens were also shown by Mr. W. Thompson, Dr. T. Wardrop Griffith, Mr. Littlewood, Professor A. S. F. Grünbaum, Dr. W. Edgecombe, Dr. Hellier, and Dr. Allan.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on April 30th, Mr. T. H. Bickerton, the President, being in the chair.—Mr. Colin Campbell read a case of Abscess of the Lung following Pneumonia successfully treated by intra-tracheal injections of izal.—Dr. J. Lloyd Roberts read a paper on Chronic Colitis with special reference to Pericolitis Sinistra. He expressed the opinion that this affection was more common than generally thought and deserved more attention. Pericolitis might occur in an acute or chronic form. The acute was usually circumscribed and arose from ulceration of the mucous membrane of the colon, which might be stercoral, traumatic, tuberculous, dysenteric, typhoid, or malignant in character. It spread through the walls of the bowel and led to circumscribed tumours outside and in contact with them. These tumours had often been mistaken for malignant growth. Occasionally the inflammatory product spread round the bowel and caused obstruction. These tumours were capable of resolution under appropriate treatment, as occurred in two cases of which details were given. Occasionally they suppurated and formed abscesses which burrowed along the length of the bowel. Two cases were mentioned in which abscesses were diagnosed and opened one near the splenic flexure and one in relation to the iliac colon. Rarely

In Section III. will be found a consideration of the myopathies (muscular dystrophies), an important group of cases presenting interesting peculiarities.

Section IV. comprises the diseases of the spinal cord. The author adopts the convenient practical division of system lesions and non-system lesions, so classifying the diseases according to the anatomical distribution of their lesions. This plan forms a useful working basis and serves as an aid to memory. In the chapter on locomotor ataxy he gives an able summary of the three main hypotheses concerning the causation of the disease. That the disease is due to (1) syphilis, acting indirectly by lowering the vitality of the nerve fibres, and not through any of the processes which are recognised as belonging to the secondary or tertiary stages of the disease; (2) syphilitic thickening of the membranes round the posterior roots, by which the nerve fibres are constricted and destroyed; and (3) the products of a bacillus closely resembling the diphtheria bacillus (Klebs-Löffler). The author points out that the acceptance of the third hypothesis is not necessarily antagonistic to the truth of the first, for syphilis may prepare the way for the invasion of other toxins, and he considers that there is strong evidence in support of this view.

Organic diseases of the brain are described in Section V., the localisation of cerebral tumours receiving especial attention. The sixth and last section is occupied with a description of diseases of functional and general origin. Epilepsy and its treatment forms an important subject, the therapeutic aspect being well discussed. The remarks on neurasthenia are also worthy of note, the clinical phenomena being well portrayed.

The book is excellently illustrated; a large number of the photographs are from cases which have been under the author's own care and are beautifully reproduced, and others have been supplied by Professor Pierre Marie and Mr. J. Bland-Sutton. We can recommend this work not only to students but also to practitioners as one in which a vast amount of information is contained in a readable form and from which much knowledge with regard to the clinical aspect of diseases of the nervous system and full instruction as to treatment may be readily obtained.

Syphilis in the Army. By Major H. C. FRENCH, R.A.M.C. London: John Bale, Sons, and Danielsson, Limited. Pp. 126. Price 6s. net.

THIS interesting work is an amplification of a former memorandum published in India and forwarded by the author in July, 1903, to the War Office, regarding the urgent necessity of revising the collection of statistics dealing with venereal diseases in the army. Certain writers have attempted to prove "that the history of the Contagious Diseases Acts in Hindustan shows that they have increased the amount of syphilis to an alarming extent amongst our unfortunate celibate troops." How such an opinion can be promulgated by any medical writer who possesses an unbiased mind is beyond comprehension. At any rate, the numerous statistics collected in this admirable work distinctly prove the contrary. The effect of preventive measures in India from October, 1898, up to the present date, unquestionably demonstrates the good effect of control to all unbiased persons. But all sources of error in the collection of venereal statistics in the army must be obviated by a correct nomenclature. The more exact diagnosis of primary syphilis and soft chancre is essential; an accurate record of readmission into hospital due to relapse of cases of secondary syphilis must be kept, showing that they are readmissions. In India the Lock Hospital system was in force from 1865 to 1884; it was partially suspended in 1884 and was abolished in 1888. From 1888 to 1898 there was consequently a marked increase of venereal prevalence. The army sanitary committee in March, 1897, acknowledges the effect of the former Acts in India in "checking not only the increase of syphilis but also the severity of the disease itself."

The home Government, however, was influenced to abolish the necessary precautions taken for the well-being of the British soldier in India by the sensational reports of certain American ladies visiting India; the result was that so great an amount of preventable disease broke out that, after a few years, the new order from home resulted in a daily amount of venereal disease in hospital equivalent to the strength of three British regiments. The order had to be modified.

Major French shows in his work the method of prevention in Indian cantonments and makes some wise remarks concerning the new messing regulations, whereby the men becoming possessed of a sum of hard cash have money to spend in brothels, and he incidentally draws attention also to the case of enteric fever contracted at the same time as venereal disease. He advocates rewards to men showing a clean medical history sheet over a fixed period as regards these affections. Next, the subject of prevention by administrative methods in military hospitals, barracks, and prisons is considered, and, finally, treatment is very fully gone into. Inunction, injection, and administration of mercury by the mouth, treatment by iodide of potassium, and the Zittmann method are all considered and criticised. Lastly, the work ends with the inclusion of various valuable appendices; we may draw especial attention to Appendix V., showing the excellent effect of control under the Cantonment Act of October, 1897. In 1897, when this was not in vogue, there were 106·2 cases per 1000 of secondary syphilis; by 1904, when the Act had been in operation for six years, there had been a regular yearly decrease of admissions to 46·7 per 1000.

LIBRARY TABLE.

The Bombay Bacteriological Laboratory for the Preparation and Use of the Anti-plague Vaccine. Printed at the *Bombay Times* Press. 1907. Pp. 39.—This excellent pamphlet has been prepared for the use of those who are called upon to carry out measures for preventing the spread of plague in India. It has been written after a prolonged and extensive experience of the disease now extending over ten years. Hence the details of the facts put forward are invested with some authority. The laboratory has fully justified its existence. Originally started by that benefactor to India, Mr. Haffkine, the discoverer of the anti-plague vaccine, on Oct. 8th, 1896, a fortnight after plague had been officially declared to exist in Bombay, it has grown from a small institution to one of considerable dimensions. It was for some time known as the *Plague Research Laboratory* but now its name has been changed into that of the Bombay Bacteriological Laboratory, a wider field of investigation and research being undertaken at the institution. Here Mr. Haffkine first elaborated his "plague prophylactic" which has saved the lives of many thousands of human beings; here, also, were made the discoveries in connexion with the etiology of plague by a commission working on the facts and materials accumulated after ten years of patient research and labour on the part of the staff of the laboratory. Whilst India has been sorely smitten by this disease she has nevertheless been the leader in advancing our knowledge of its cause and prevention, and this laboratory has played no small part in the attainment of this position. The brochure opens by detailing the facts to be borne in mind when determining the anti-plague measures to be adopted. These may be classed into (1) measures of permanent utility affecting the habits of rats and of men bringing about the association of one with the other; and (2) measures of temporary utility, such as the destruction of rats, evacuation, and inoculation. Next is demonstrated the effect of inoculation with anti-plague vaccine, and here we find detailed the educational value in a direct acquaintance with an important original paper which is lost in even the best of abstracts or reviews.

The nucleus of the book consists in the section contributed by Dr. Graham-Smith, which has in great part already appeared in the *Journal of Hygiene*, also published by the Cambridge Press. Around this nucleus have been grouped a history of diphtheria written by Professor Löffler, than whom none is more fitted for the task; a section on the epidemiology of the disease, by Dr. Arthur Newsholme; a section on its pathology, by Professor Mallory, based largely on a monograph by Councilman, Mallory, and Pearce; a very valuable contribution by Dr. G. Dean on toxins and antitoxins; and, finally, a section by Dr. William H. Park and Dr. C. F. Bolduan on mortality and serum sickness. The editors are to be congratulated on having secured such contributors, and the list of names makes it evident that the reviewer can only profitably concern himself with the general aims of the book and not with the statements made. The method of the book makes detailed review still less necessary, as the well-established facts are given definitely and briefly; controversial matters are discussed at length with the arguments on both sides; and finally, full references are given to the authorities for the statements which are made. The editors have not been able to secure absolute agreement amongst their contributors, especially in the two sections which deal with the epidemiology of the disease, and there is some repetition, as in two sections besides that devoted to the history there are short historical accounts. This may have arisen from the desire to make each section complete in itself.

The section by Professor Löffler is of great interest and is marked by Teutonic thoroughness. The part played by Francis Home in defining and calling attention to the disease is fully appreciated and, as might be expected, the history of the bacteriology of the disease is most complete. In the epidemiological section Dr. Newsholme develops his conclusions as to the relation existing between rainfall and diphtheria epidemics, conclusions which are by no means accepted by the contributors of the last section of the book and which seem to be in contradiction with the conditions existing in the epidemics studied by Bretonneau and his contemporaries. Professor Mallory deals in his section with the lesions found in the various tissues and organs of those suffering from the natural and experimental disease. Dr. Graham-Smith's section deals fully with the variable morphology of the diphtheria bacillus and with the differential characters of its cultures. There is also a valuable discussion of the very numerous diphtheria-like organisms which, as workers in clinical laboratories know to their cost, are found in all kinds of secretions and are liable to give rise to errors of diagnosis when, as is usual owing to the exigencies of practice, diagnosis rests on morphological appearances alone. This question has acquired fresh importance since it is evident from recent literature that the relation of human diphtheria to similar diseases in the lower animals is not so definitely settled as is desirable. To the medical officer of health and the physician the detailed accounts of the investigation of various epidemics, chiefly in the eastern counties, and of the preventive measures suggested and adopted, will prove of much interest and value.

The section by Dr. Dean is one of the most valuable in the book and is characterised by the care and thoroughness which mark all the contributions to science of this observer. It contains original work and personal experience gained in the superintendence of the serum department of the Lister Institute and in addition to its proper subject of diphtheria toxins and antitoxins necessarily trenches on general questions of immunity. The serum sickness dealt with by Dr. Park and Dr. Bolduan is a very interesting subject which is, however, still in a very early stage of investigation and far from being fully elucidated. Portraits and short biographical notices of Bretonneau, Löffler, Behring, and Roux add to the interest and completeness of the volume.

The book is of somewhat imposing size and is neatly bound in dark-blue canvas. It is well and clearly printed on good paper and contains a considerable number of well-reproduced illustrations. There is a mistaken reference on p. 487 and an error of more importance occurs in the explanation of the method of reference adopted in the bibliography, though the error is easily corrected. The bibliography is very complete and there is a good index.

Diseases of the Nervous System. By H. CAMPBELL THOMSON, M.D. Lond., F.R.C.P. Lond., Physician to Out-patients at the Middlesex Hospital; Dean of, and Medical Tutor in, the Middlesex Hospital Medical School; Physician to the Bolingbroke Hospital and to the Hospital for Epilepsy and Paralysis, Maida Vale. With 8 coloured and 12 black-and-white plates and 101 figures in the text. London: Cassell and Co., Limited. 1908. Pp. 480. Price 10*s.* 6*d.*

A STUDY of the diseases of the nervous system presents considerable difficulties to the student. These difficulties mainly arise from the variety and multiplicity of the symptoms, the pitfalls that readily occur in differential diagnosis, especially in distinguishing between functional and organic disease, and the long and uncertain course of some of the affections coming under this head. In the volume now before us Dr. Campbell Thomson has attempted to marshal, more especially for the benefit of students, the main facts of neurology in a concise and readable manner. After a careful perusal of the work we are able to congratulate the author on the success of his endeavours. Without wading through pages of controversial matter or being confronted with profound propositions in etiology and pathology, the student is able to obtain clear ideas as to the causation, morbid anatomy, symptoms, clinical course, diagnosis, prognosis, and treatment of diseases of the nervous system.

The first section of the book is introductory and gives a brief but comprehensible account of the general structure of the nervous system, together with chapters on the reflexes, rigidity, and contractures, and some remarks on electrical reactions. Some observations are also offered on lumbar puncture. Dr. Campbell Thomson states that by examination of the cerebro-spinal fluid lymphocytosis can often be demonstrated in the early stages of general paralysis of the insane, tabes dorsalis, and syphilitic diseases of the nervous system. It has also been found in disseminated sclerosis and anterior poliomyelitis. We agree with the author in the opinion that undue stress must not be laid on this method of diagnosis, and in all doubtful cases the results should be carefully considered in conjunction with the other phenomena before a decision is arrived at. Dr. Campbell Thomson very properly lays stress on the importance to students of distinguishing between lesions affecting the upper and lower neurons respectively, and gives a summary in tabular form of the differences to be observed. The advantage of this table is that the student will find in it the basis of all the symptoms which depend upon loss of power, and instead of endeavouring to remember a different set of points for every individual instance he can apply the general principles to any particular case and then supply the details as required.

Section II. is concerned with the peripheral nerves, and a good account is given of paralysis of cranial nerves and of paralyses of the upper and lower limbs. The chapter on multiple neuritis is well worthy of study, the descriptions of the symptoms due to the action of alcohol, arsenic, and lead being clear and precise.

JOURNALS AND MAGAZINES.

Proceedings of the Royal Society of Medicine. April, Vol. I., No. 6.—These proceedings continue to maintain their level of excellence. The present number is largely concerned with accounts of cases, many of which have been reported in our columns, the Clinical, Dermatological, Laryngological, Neurological, and Odontological sections each contributing cases of great interest. In the Epidemiological Section an important discussion on the Etiology and Epidemiology of Enteric Fever is opened by Dr. E. C. Seaton and continued by Dr. D. S. Davies with Dr. I. Walker Hall, who deal with Typhoid Carriers, by Dr. H. M. Richards with Dr. J. A. H. Brincker dealing with the Potential Dangers of Waters derived from Wells in the Chalk, and by Dr. W. H. Hamer who writes on the Relation of the Bacillus Typhosus to Typhoid Fever, papers which are followed by a report of the general discussion. Two papers are communicated to the Medical Section; the first is by Dr. G. S. Shattock and Dr. Arthur Latham and deals with Phagocytosis, especially in reference to infectious disease, the observations having been made by means of melanin. The second is by Dr. Latham and is a preliminary communication upon the Administration of Tuberculin and other Vaccines by the Mouth, a subject of considerable interest. In the Obstetrical and Gynæcological Section, besides the reports of cases, papers are contributed by Dr. W. C. Swayne on Abdominal Myomectomy during Pregnancy, by Dr. John H. Dauber upon Pregnancy complicated by Large Myomata, and upon a case of Difficult Labour by Dr. H. Russell Andrews with Dr. R. Drummond Maxwell. In the Dental Section Mr. E. Sturridge deals with the treatment of Pyorrhœa, and the discussion upon Mr. J. F. Colyer's recent paper dealing with the Treatment of Children from the Dental Aspect is reported. In the Otological Section Mr. C. E. West and Mr. Sydney R. Scott together write upon the Operative Surgery of Labyrinthitis, and Mr. H. H. B. Cunningham upon Deafness resulting from Epidemic Cerebro-spinal Meningitis. In the Pathological Section Mr. C. E. Walker treats of the Influence of the Testis in the Secondary Sexual Characters of Fowls, and a discussion on the Relations of Endotheliomata to Other Forms of New Growths is opened by Dr. W. S. Lazarus-Barlow and continued by Mr. L. Cortauld with Mr. A. Leitch and Mr. Cecil W. Rowntree. The Surgical Section is devoted to Mr. A. E. J. Barker's paper upon the Possible Uses of Lumbar Puncture in the Treatment of Otitic Meningitis, whilst the Therapeutical Section is occupied with a paper on Hypnotism by Dr. J. Milne Bramwell, which includes a historical summary of the therapeutic employment of that much-debated measure.

Ophthalmology. Vol. IV., No. 3. April, 1908. H. V. WÜRDEMAN, Managing Editor, Milwaukee, Wis., U.S.A. Issued quarterly. London: George Keener and Co. Annual subscription £1 1*s*.—The original articles contained in this number of *Ophthalmology* are: 1. Report on Three Cases presenting Ocular Manifestations of Tertiary Syphilis in Coloured Subjects, by W. Campbell Posey and Frederick Krauss, M.D., of Philadelphia. One of these cases exhibited syphilitic arteritis of the retina with optic atrophy; the second, cerebro-spinal syphilis with complete palsy of the left oculo-motor and trochlearis nerves—this case rapidly improved under antisyphilitic treatment; and the third case showed complete palsy of the third nerve, with cessation of head pain with the concomitant appearance of double vision. 2. The Centume System, the Percentage or Nomenclature of Angles, by Ernest E. Maddox; a valuable suggestion. 3. Insufficient Pigmentation as a Cause of Eye Diseases, by Charles E. Woodruff, M.D. 4. Remarks on Vibratory Massage in Eye Diseases, by Leartus Connor, M.D. This method of treatment is said to be useful even in glaucoma. 5. Morax Axenfeld Conjunctivitis, an analysis of 300 cases, by Hanford McKee, M.D. 6. The Evil Eye among the Hebrews, by Aaron Brav, M.D.; an interesting article showing considerable research. 7. Verhoeff's Astigmatic Charts. 8. The Relation of the Eye and the Nose, by Harry Caldwell Parker, M.D. In addition are numerous abstracts from recent ophthalmic literature and brief reviews of books.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., ALEX. MACALISTER, D. J. CUNNINGHAM, ARTHUR THOMSON, and ARTHUR KEITH. Vol. XLII. Third series, Vol. III., Part 3. April, 1908. London: Charles Griffin and Co. Published quarterly. Annual subscription, £1 1*s*., post free.—The articles contained in this number are: 1. A description of a Human Embryo of 13-14 Mesodermic Somites, by Dr. Alexander Low. 2. Studies in the Anatomy of the Pelvis, with special reference to the fascia and visceral supports, by Professor G. Elliot Smith, F.R.S. (Part II.). 3. The Brains of Aboriginal Natives of Australia in the Anatomy School, Cambridge University, by Dr. W. H. Duckworth (Part III.). 4. The Development of the Spleen, by Marion Radford. 5. The Comparative Anatomy, gross and minute, of the Thyroid and Parathyroid Glands in Mammals and Birds, by Dr. David Forsyth (Part II.). 6. Imperfect Torsion of the Intestinal Loop, by Dr. Douglas G. Reid. 7. The Derivation of the Human Hypothenar Muscles, by Mr. J. Ernest Frazer. 8. The Cameragraph; a Drawing Apparatus, by Evelyn John Evatt. 9. Two Cases of Normaphroditism, by Dr. Strickland Goodall. 10. A Case of Fusion of the Semilunar and Cuneiform Bones (Os Lunato-Triquetrum) in an Australian Aboriginal, by Dr. S. A. Smith. There are in addition to the above articles some Anatomical Notes on the Small Vermiform Appendix, by Mr. Sidney R. Scott; on an Abnormal Form of Duodenum, by Mr. Gordon Taylor; and on Meckel's Diverticulum, by Mr. F. G. Parsons.

The Biochemical Journal. Edited by BENJAMIN MOORE, M.A., D.Sc., and EDWARD WHITLEY. Vol. III., No. 3. April 16th, 1908. Biochemical Department, Johnston Laboratories, University of Liverpool. Pp. 57. Annual subscription, 15*s*.—This number contains the following original articles: 1. Observations on the Significance of the Hæmosozoic Value of the Blood Serum, by Captain D. McCay, I.M.S., Professor of Physiology, Medical College, Calcutta. The term hæmosozoic value of the serum has been made use of to indicate those constituents present in the serum which preserve the red blood corpuscles from solution. Captain McCay finds that the hæmosozoic value of the serum expressed in terms of NaCl corresponds with the total salt concentration. When the hæmosozoic value is increased above the normal it is a measure of the total salt concentration, and also of the presence of a substance which he believes to be an antihæmolysin. The lowering of the value is a factor in inducing an attack of blackwater fever. On the other hand, the raising of the value by the administration of chlorides, quinine, and so on, would appear to be prophylactic against that disease. 2. On Variations Observed in the Composition of Sodium Glycocholate Preparedby Different Methods, by W. C. Lewis, M.A. The author endeavours to show that as ordinarily obtained the salts of other acids probably, and chiefly sodium myristate, are present. 3. Notes on the Action of Atropine, Hyoscyamine, Hyoscine, Scopolamine, Duboisine, and Daturine, by Dr. W. Webster, anæsthetist to the Winnipeg General Hospital. Dr. Webster finds that there is no initial rise in blood pressure after the injection of solution of atropine beyond what would be caused by the injection of a corresponding amount of normal saline solution. The effect in the case of this series of drugs is always a fall of experience of towns, employers of labour, railway companies, military authorities, police, and jails. Then a popular account is given of the mechanism by which anti-plague vaccine effects a saving of life in the presence of plague, followed by a consideration of the question whether anti-plague inoculation should be carried out in the presence of the disease. The protection conferred by inoculation is stated to last to a slight extent even after five years. It is also shown that the practice gives rise to no disease and that it does not affect the health of those inoculated in any way injuriously. The method of preparing the vaccine is succinctly detailed, after which the immediate question of inoculation is taken up, including the symptoms produced by it, the dose of the vaccine to be employed and how to sterilise and to fill the syringe, and how to carry out the actual act of injection. The work though small forms a complete guide to the subject of which it treats.

The Pocket Osteology. By PHILIP TURNER, M.B., M.S., B.Sc. Lond., F.R.C.S. Eng., Demonstrator of Anatomy, Guy's Hospital. London: Baillière, Tindall, and Cox. 1908. Pp. 187. Price 3*s.* net.—The student preparing for his second professional examination who is wont to carry the recently re-named "Pocket Anatomy" in its appropriate receptacle will now be able to preserve the balance of his garment with a volume of identical size and form which is strictly complementary to his older *vade mecum.* Although Mr. Turner's pocket compendium of osteology is of no greater bulk than its predecessor it does not present quite so remarkable an effort of condensation as does that favourite epitome of the soft parts, on account of its more limited range of subject matter. This "Pocket Osteology" is admittedly produced by a boiling-down process from the various standard text-books, but it has been excellently done by a writer well qualified to do it who would be the last person to wish to replace those text-books. The absence of pictures renders reference to actual bones imperative for its intelligent employment, and if this were not the case we do not think the student would be tempted to use it except as an aid to revision. The man who attempted to "learn his bones" from this pocket-book alone would find in them a mental pabulum of intolerable dryness. It has a legitimate use as a supplement to the manuals in use in the dissecting-room.

Early Woodcut Initials. Containing over 1300 reproductions of ornamental letters of the fifteenth and sixteenth centuries, selected and annotated by W. OSCAR JENNINGS, M.D. Paris. London: Methuen and Co. 1908. Pp. 288. Price 21*s.* net.—All lovers of books owe to Dr. Jennings a debt of gratitude for his delightful storehouse of initial letters. The reproductions of these works of art are introduced by a scholarly preface in which Dr. Jennings describes the precursors of the wood-cut initial—namely, the illuminated initial. He does not mention one school, however, in which fancy and imagination, together with intricacy of design, yet with no confusion, were at their best, and that was the Mozarabic school of 800–1000 A.D. The British Museum possesses some liturgies of surpassing interest as to their initials which are well worth attention. The elaborate decoration of the initial letters occurring in early printed books by means of wood-engravings forms an interesting link between the centuries in which the multiplication of books was the outcome of monastic handicraft and often of remarkable art and our own days in which for the greater part it has drifted into strictly utilitarian channels, with a sad sacrifice of beauty to convenience. We are pleased to qualify this remark by saying that the book before us is a fine production of Messrs. Constable's press and is sufficient of itself to prove that the art of making beautiful books is not buried in the centuries, however the modern methods may differ from the old ones with which the book is concerned. It is quite obvious from a study of black-letter volumes that the original printers modelled their work on the manuscripts to which their fathers were accustomed; and as the exquisite elaboration and adornment of the capital letters formed, perhaps, the most striking feature of all illuminated and many plain manuscripts, it is not surprising that the pioneers of a mechanical process which was to replace the scribe should strive to reproduce his most remarkable achievements. By means of this book Dr. Jennings shows in what measure they succeeded. The charm of their work lies undoubtedly in the fact that although it entailed mechanical aid it was still primarily handicraft, for they drew and graved upon wood what the scribe drew and painted upon vellum. But whatever pleasure these pictured initials may give us, and many of them are excellent in design and execution, it cannot be compared with the surpassing delight afforded by the illuminated miniatures which fulfil the same office in the Missals and Horæ written in the thirteenth and fourteenth centuries. Nevertheless, the initials which Dr. Jennings has reproduced so liberally in his book form a collection which shows forth almost every phase of the artistic mind. We find conventional design endowed with elaborate beauty and Early German work breathing a piety and sincerity worthy of Blake himself; the influence of the Renaissance peeps out on other pages with its strange juxtaposition of paganism and Christian legend manifest in the pictures so ingeniously woven into or around the curious capitals; the fanciful is well represented, running often into the grotesque and on certain pages the formal verging on the ugly, whilst the luxurious over-elaboration of other specimens points to the rococo influence that played such havoc with post-Renaissance art. Dr. Jennings has derived his examples from the presses of Augsburg, Nuremberg, Basle, Lubeck, Strasburg, Geneva, Venice, Lyons, Paris, Rouen, and other towns. England is represented in four pages which as examples of art do not bear comparison with those devoted to the remaining countries. We know of no book which affords a more interesting and diverse catena of an important European handicraft during its best period, and we must add that Dr. Jennings's letterpress shows full information of a subject which has of necessity a limited appeal. It is, however, the work of an enthusiast who has the satisfaction of knowing that he has very literally enriched the year's output of the *belles lettres* in this country.

The Public Schools Year Book, 1908. London: Swan Sonnenschein and Co. Pp. 684. Price 3*s.* 6*d.* net.—This book is a useful addition to the reference shelf, giving compact information as to the staff and curriculums of the different public schools, a list of preparatory schools, and succinct information as to the gates of entry and prospects of success in the various professions. The chapter on the medical profession has been carefully done and gives in a summary form the information which parents and guardians might expect concerning the chances of their sons who embrace medicine as a career.

Herbert Fry's Royal Guide to the London Charities. Forty-fourth issue. Edited by JOHN LANE. London: Chatto and Windus. 1908. Pp. ix.-383. Price 1*s.* 6*d.* net.—This is the oldest publication of its kind dealing with the metropolis and contains an alphabetical list of the London charities, showing their date of foundation, address, objects, annual income, and chief officials according to their latest reports; a vast amount of information is summarised in convenient form. We note that the "London and Provincial Anti-Vivisection Society" and the Vivisection (National Anti-) Society are for some inscrutable reason included in the list of charities.

THE LANCET.

LONDON: SATURDAY, MAY 16, 1908.

The Administration of Bacterial Vaccines by the Mouth.

THE interesting and suggestive work of Sir ALMROTH E. WRIGHT and his co-workers has led to a greatly extended use of bacterial products or vaccines in the treatment of morbid conditions due to bacterial invasion and has established this form of treatment on a more assured and scientific basis than it had previously enjoyed. Whatever the exact and absolute practical value of the opsonic index may prove to be as a guide and control in administering vaccines for diagnosis and treatment, the impetus which it has afforded to their use constitutes a noteworthy achievement in rational and scientific medicine. At the same time it must be admitted that the frequent determinations of the opsonic index necessitated by a prolonged course of vaccine treatment involve an expenditure of time on the part of a skilled observer and an expenditure of money on the part of the patient which tend to hinder the wider employment of the treatment. Dr. ARTHUR LATHAM, in an interesting communication read before the Medical Section of the Royal Society of Medicine[1] on March 24th recording a series of observations made in conjunction with Dr. H. R. D. SPITTA and Dr. A. C. INMAN, maintains that the use of tuberculin and of other vaccines has not been adopted sufficiently, and suggests that this is due to the necessity for employing the hypodermic method of administration and for the frequent estimations of the opsonic index to which reference has already been made. Dr. LATHAM'S objects in his research were to overcome these difficulties and to simplify the technique of treatment by vaccines. Undeterred by the statement made by KOCH some years ago that tuberculin administered by the mouth would not confer immunity, he proceeded to administer it and other vaccines in this manner, arguing that they would probably be absorbed if given on an empty stomach together with some substance which would facilitate absorption, such as normal saline solution or horse serum. Dr. LATHAM further argued that, since there is now very strong evidence that some cases of pulmonary tuberculosis are brought about by the absorption of living bacilli from the alimentary canal, it was reasonable to suppose that the absorption of dead bacilli or of their products would likewise occur and that they would excite the protective mechanisms of the body. This assumption received important experimental confirmation in a paper by CALMETTE, GUÉRIN, and BRETON, published some two months after Dr. LATHAM commenced his own *clinical* observations, in which it was shown that the administration of specially prepared emulsions of dead tubercle bacilli conferred immunity on guinea-pigs, provided that the emulsion was not given together with food.

Dr. LATHAM'S paper contains records of a number of cases, 25 in all, of various infections, chiefly tuberculous, staphylococcal and pneumococcal, in which he administered appropriate vaccines by the mouth and sometimes by the rectum, together with normal saline solution or horse serum, and then studied the effects upon the clinical course of the cases, upon the temperature curve, and also upon the opsonic index. In the course of his observations many hundreds of opsonic index determinations were made by Dr. SPITTA and by Dr. INMAN, so that the laborious nature of the work is obvious, and Dr. LATHAM pays a well-deserved tribute to the assistance which he has received in this respect from his collaborators. We may briefly review some of the chief results claimed to have been obtained. In regard to the use of tuberculin only one form has been employed in this research—viz., tuberculin T.R. When given by the mouth, even in so small a dose as 1/10000th of a milligramme, together with normal saline solution or some other agent to facilitate absorption, it produces a definite effect upon the opsonic content of the blood. The negative phase produced after oral administration appears in general to be shorter and less marked than that after hypodermic administration, and the positive phase is also shorter, rarely lasting more than five days, often to be followed by a further short negative phase and a more prolonged positive phase. Coincidently with these changes there is an improvement in the clinical features of the cases if the doses of tuberculin are suitably administered so as to avoid overdosage or too frequent repetition. The temperature falls, the cough becomes less troublesome, expectoration is diminished, and the patient has a sense of well-being. A further noteworthy point is that in three cases with the inverse type of pyrexia the administration of tuberculin brought about a return to the ordinary type. Dr. LATHAM recommends that tuberculin should always be given on an empty stomach and best in the morning when the resistance is highest. In regard to dosage, he states that the investigations have not progressed to a sufficient extent to enable definite rules to be formulated but the condition of the patient and the temperature chart afford important indications. If the dose chosen does good the patient feels better and the temperature falls, while the other symptoms improve. If the dose is too large the patient quickly complains of headache, his appetite fails, and he becomes listless, though there may be but little rise of temperature. If the dose be much beyond what is needed there may be in addition a definite rise of temperature. The smallest dose given in these cases was 1/10000th of a milligramme and the largest was 1/200th. In some cases doses of 1/5000th of a milligramme or 1/1000th have been given on two or three successive days with good results. In febrile cases it is necessary to proceed with greater caution both in regard to the dose and to the frequency of administration than in localised or afebrile cases. It is of special importance to avoid any attempt to hurry on the treatment in these matters, since overdosage has in the past been responsible for the discredit which overtook the vaccine treatment by tuberculin after its first introduction. In regard to the administration of staphylococcal and streptococcal vaccines by the mouth it is claimed that the same results are obtained as on hypodermic injection the blood pressure. 4. A Note on the Distribution of the Salts in Hæmolysis, by Dr. Albert Woelfel, from the Hull Physiological Laboratory, Chicago.

---

[1] Proceedings of the Royal Society of Medicine, vol. i., No. 6., p. 195.

The Scottish Medical and Surgical Journal.—In the April issue is published the first instalment of an article by Dr. A. H. F. Barbour on the Frozen Sections made by Bumm and Blumreich and by Zangemeister and the question as to whether there is a lower uterine segment. Mr. David M. Greig records a case of Henoch's purpura which simulated intussusception; there were pain, vomiting, and diarrhœa, with passage of blood from the bowel and the presence of a palpable lump in the right iliac fossa. At the laparotomy this last was found to be due to "great congestion of the lower end of the ileum which projected as a distinct collar into the cæcum." Dr. J. Wallace Milne gives notes of a case of chronic intussusception in a girl, aged ten years, who recovered after resection of a portion of the bowel; and Dr. Norman Walker discusses the use of chrysarobin in psoriasis in a paper which is illustrated by a very good coloured picture of the untreated disease, as well as by some others showing the results of treatment.

The West London Medical Journal.—The April number of this quarterly journal contains an article by Dr. Andrew Wylie on the causes, pathology, and treatment of foul breath. Mr. W. H. Bowen writes on pneumococcal otitis media, and among other causes blames the too familiar "infant's comforter" for some instances of infection. An abstract of two lectures by Dr. Harold Pritchard on specific inoculation does not add much to our knowledge on this subject.

The Medical Chronicle.—Only one original article appears in the April number of this magazine. In it Mr. H. W. Bruce and Mr. H. H. Rayner record two cases of acute glanders. The second case was remarkable in that no connexion of the patient with horses could be traced. In both diagnosis was difficult, as the characteristic pustular eruption did not appear till late in the course of the malady.

Guy's Hospital Gazette.—In the issue for April 4th the most interesting article is one entitled, "Notes of a Roving Guy's Man," which deals with the writer's experiences in Berlin and gives an account of the methods there adopted for medical study and of some of the cases demonstrated by Professor Pels-Leusden. A dental clinical lecture by Mr. J. Lewin Payne deals with the treatment and filling of root-canals. In the following number (April 18th) is an account by Dr. Hertz of the hospitals of Paris, which is to be continued in the next issue. A clinical lecture by Mr. Ormond deals with cataract extraction and gives a tabular statement of the results of 50 consecutive cases.

St. Bartholomew's Hospital Gazette.—In the April number is published a lecture by Dr. H. Morley Fletcher on whooping-cough. By way of treatment he speaks favourably of creasote and cresolene for inhalation and of belladonna as the main drug for internal use. Antipyrin, bromoform, butyl, chloral, and liquid extract of grindelia are also useful. An abstract of a lecture on art and medicine, by Dr. Leonard P. Mark, contains some interesting reading and is illustrated by some reproductions of celebrated paintings.

St. Thomas's Hospital Gazette.—In the March number of this periodical is an interesting paper by Mr. Edred M. Corner on the modern treatment of fractures by means of direct internal splintage—that is to say, by wiring and so forth. It is illustrated by skiagrams showing the apparatus *in situ.*

The London Hospital Gazette.—In the March issue appears a clinical lecture signed "F. J. S." on the subject of medical hæmorrhage, with special reference to hæmatemesis and gastric ulcer. The indications for surgical interference are considered. May we suggest that members of a learned profession should not write *per orem* for by the mouth? Two unusual cases of injury to joints are recorded on another page—one of separation of the capitellum of the humerus and the other of dislocation forwards of the whole foot at the ankle-joint.

St. George's Hospital Gazette.—The March number opens with a further instalment of the paper on ancient medicine, which contains much that is of interest. A note on medical practice at sea, by Mr. Hamilton S. Faber, is also worthy of the attention of those who meditate "going down to the sea in ships" in the capacity of medical officers; it gives a by no means unattractive picture of the life and duties.

LYNN THOMAS AND SKYRME FUND.

THE following subscriptions have been received between May 2nd and May 8th by Mr. William Sheen, M.S. Lond., F.R.C.S. Eng. (2, St. Andrew's-crescent, Cardiff), honorary secretary to the fund.

Subscriber of Five Pounds.

L. A. R. Wallace, London.

Subscribers of Three Pounds Five Shillings.

Glossop and District Medical Society Members, per Arthur Walker.

Subscriber of Two Pounds Ten Shillings.

Victoria Central Hospital Staff, per D. Malcolm Smith, Liscard.

Subscriber of Two Guineas.

Lieutenant Owen Berkeley Hill, I.M.S., Bangalore, India.

Subscribers of One Guinea.

Beaumont and Trevor, London.
Arthur Burton, Cromer.
Ernest Carter, Cheltenham.
Ernest H. Cartwright, Ticehurst, Suesex.
Henry W. Drew, East Croydon.
Theodore Duka, Bournemouth.
W. E. Nickolls Dunn, London.
George Fuller England, Winchester.
Thomas Evans Flitcroft, Bolton.
William T. Gardner, Bournemouth.
Thomas Fred Higgs, Dudley.
J. O. Hollick, Knowle, near Birmingham.
G. Wright Hutchison, Chipping Norton, Oxon.
Keighley and District Medico-Chirurgical Society, per Alfred G. Hebblethwaite.
G. Lloyd Jones, Cambridge.
G. A. Leon, Sidmouth.
Ernest C. Maguire, Brighton.
Gervase G. Newby, East Croydon.
W. G. Scott, *Newton Abbott.*
J. H. Sequeira, London.
J. O. Skevington, Windsor.
R. Percy Smith, London.
Charles Steele, Bristol.
J. Connall Wilson, Haworth, near Keighley.

Subscriber of One Pound.

Logan D. H. Russell, Bristol.

Subscribers of Half-a-Guinea.

M. D. French, Burslem.
M. Iles, Bhopal, India.
Thomas John, Swansea.
Walter J. Jolliffe, Shorewell, Isle of Wight.
A. Hill Joseph, Bexhill-on-Sea.
Launcelot E. Jowers, St. Leonards-by-the-Sea.
W. Lockwood, Worthing.
A. Angus Martin, North Shields.
J. W. Meek, London.
Gay Witton Miller, North Thoresby, S.O., Lincs.
William P. Morgan, Seaford, Sussex.
Joseph O'Connor, St. Anne's-on-the-Sea.
T. Richards, Cardiff.
T. W. E. Ross, Cardiff.

Subscribers of Ten Shillings.

DONATIONS AND BEQUESTS.—Under the will of the late Mr. Thomas Webb of Cardiff, University College, London, will receive £5000 to be used and applied, so far as is practicable, for the purposes of physical research; University College of South Wales and Monmouthshire £5000 for a similar purpose; and £500 are bequeathed to the Cardiff General Infirmary and £500 to the General Hospital, Tunbridge Wells.—By his will Mr. Caleb Ashworth Tate of West Dulwich has bequeathed £5000 each to the National Hospital for the Paralysed and Epileptic and the National Society for the Employment of the Epileptic.—The late Mr. R. H. Wood of Sidmouth has bequeathed £1000 to the funds of the West of England Eye Infirmary, Exeter.

The circumstances, indeed, which have occasioned the appointment of the Departmental Committee are in themselves ample proof of this, for, as the terms of reference plainly intimate when they allude to the inquiry as "involving questions of urgency," it is clear that the immediate *raison d'être* of the Committee is the necessity of finding a way out of the anomalous situation created by the recent action of the London County Council which, as we have pointed out,[1] has practically suspended the operation of the Inebriates Act of 1898 in the metropolitan area. Of the importance of dealing promptly with this situation there can, of course, be no question, but it is earnestly to be hoped that the recommendations of the Committee on this point will not be limited to suggesting a basis of compromise with the Council on the financial matters in dispute but that they will be of a more radical character and will deal with the real issue in the controversy between the Council and the Government—namely, the question whether the responsibility for the control and maintenance of institutions for criminal inebriates should devolve on the State or on local authorities. Up to the passing of the Inebriates Act of 1898 the class of drunkards for whose treatment that measure was specially designed—that is to say, the ordinary police court recidivists—had been dealt with in prisons under the management and at the expense of the State. The Act in question permitted the adoption of an alternative and *ex hypothesi* a better system for the control of such persons, but at the same time delegated the responsibility for working this system to local authorities and to private individuals and placed on the rates a large part of the cost of maintaining the reformatories founded under the Act. It is difficult to gather either from the debates on the measure in Parliament or from subsequent discussions of the question the precise grounds on which this policy was adopted. The principle of local control had been tried and found wanting in prison administration and the weighty reasons which compelled the State in 1870 to take over the management of the local gaols from the county authorities would seem to apply with at least equal force to the case of reformatories for criminal drunkards. It is evident, for instance, that it is no less important in these reformatories than it is in prisons that the conditions under which sentences of compulsory detention are carried out should be, if not uniform, at all events so far similar as to obviate the risk of local exaggerations of either the humanitarian or the deterrent idea; and such similarity of conditions can hardly be secured without centralised administration. The same mode of administration commends itself also on grounds of economy, understanding, of course, by that term the true economy of which efficiency is an essential part. In the case of reformatories for inebriates such efficiency demands, above all, adequate means for the separation of the different classes of inmates; and this must obviously be a far more expensive matter under the system by which each county maintains its own reformatory where all classes of inebriates are treated, than it would be under a system which would allow all the inebriates of the country to be distributed over a number of institutions, each arranged with a view to meeting the requirements of the particular category of inebriates to be detained in it. On a limited scale these two systems are in actual operation at present and it would appear from the reports of the inspector under the Inebriates Act that the superiority of the system of centralised administration has been conclusively shown in practice. Dr. R. W. BRANTHWAITE tells us that in the reformatories which are known collectively as "The National Institutions for Inebriates" and which are under the control of a single governing body, the initial cost of construction and the *per capita* expense for maintenance are considerably lower, while the profit from the labour of the inmates is considerably higher, than in any of the reformatories founded by the county authorities. Unless, therefore, the Departmental Committee succeeds in discovering some facts not hitherto available in the discussion of this question it seems clear that the balance of evidence leans to the view that the control of inebriate reformatories is a duty which is incumbent on the State, for, of course, in institutions which will inevitably have to some extent a penal character any system of centralised administration must of necessity be under the direct control of the State. It is inconceivable that public opinion would sanction, except as a merely temporary expedient, any arrangement whereby associations of private individuals however estimable would be entrusted with the large disciplinary powers exercised under the Inebriates Act.

The zeal for clear and logical principles, none the less effective for being possibly unconscious, which has impelled the London County Council to raise in an acute form the question of administrative control which we have just discussed, will no doubt give this matter the first place on the programme of the Departmental Committee. There is perhaps on this account a certain risk that other and even more important defects in the present law relating to inebriates may not receive all the attention which they demand. The most serious of the defects to which we refer concern the definition of the habitual drunkard established by the Act of 1898. The framers of that measure appear to have overlooked the homely counsel that as the first step towards cooking your hare it is well to catch it. Their method was rather to set up an elaborate, though as we have seen a not very efficient, apparatus for catching and cooking, and then to assume that whatever found its way into their cooking pot was to be regarded as hare, and indeed as the only authentic sort of hare. Thus according to the provisions of the Act an inebriate was defined in practice as a person who, being regarded in the expert opinion of a policeman as a drunkard, was either convicted summarily three times in a twelvemonth of drunkenness or was convicted on indictment of certain offences in the perpetration of which drunkenness was supposed to be a contributory cause. By this test, therefore, an industrious and intelligent artisan with an excessive taste for conviviality on Bank Holidays might readily be committed to a reformatory for three years to be cured of inebriety, while a steady soaker who lived and worked on alcohol, but never got obtrusively drunk, might go on till he died from cirrhosis of the liver or till he killed his family and himself in an outbreak but that the duration of both the positive and the negative phase is shorter. In regard to dosage the same quantity has been employed in these observations as is recommended for hypodermic use but Dr. LATHAM suggests that it is probable that it might be slightly increased with advantage. In regard to pneumococcic infections only three cases are described and in these the administration of a dose of a stock pneumococcal vaccine in horse serum appeared to exert a favourable influence, but the observations are too few to draw any useful conclusions from; moreover, one of the cases was in a child, aged two years, with an apical pneumonia, and in such cases the pyrexial period is often short apart from any specific treatment.

---

[1] THE LANCET, March 28th, 1908, p. 949.

Dr. LATHAM next endeavours to establish whether any relationship exists between the variations of the opsonic index and those of the symptoms and temperature curve with a view to formulating rules for treatment by vaccines without the necessity for frequent opsonic determinations. He states, as a result of the observations made by himself on the clinical side controlled by those of his collaborators on the opsonic index, that the more carefully the symptoms of a patient and the curve of his temperature are studied the more accurately it can be inferred whether the opsonic index is fluctuating or is in a positive or negative phase. He summarises the relations which he claims to have established in the following general statements. In febrile cases the opsonic index fluctuates with the temperature but in an inverse direction, so that when the temperature falls the opsonic index rises, while it falls when the temperature rises. When the temperature is persistently high the opsonic index is persistently low, and when the temperature, although remaining at about the same high level, fluctuates to a less degree there is an improvement in the opsonic index. In afebrile cases there is also an inverse relation between the temperature and the opsonic index. When the temperature has been fluctuating from 97° to 98·4° F. and then remains level at 98° the opsonic index rises. When the temperature, previously level and normal or subnormal, rises to 99° the opsonic index falls. In regard to the relation to clinical symptoms it is claimed that the index is low when the patient complains of subjective symptoms, headache, restlessness, and want of appetite; it is raised when the patient feels better and his symptoms show improvement. Dr. LATHAM is confessedly somewhat vague in his statements as to the value of the horse serum which he administered together with the tuberculin in some of his cases. Control cases with vaccines given in normal saline solution have shown good results and he does not recommend the repeated use of horse serum for more than a fortnight. He is careful to describe his paper as a preliminary communication and as such it is well worthy of careful consideration. The comparatively short space of time during which most of the cases were under observation permits of little inference being drawn as to the actual curative value of the administration of tuberculin by the mouth, while in regard to the other conditions so few cases were observed that the observations can only be regarded as suggestive. The chief facts established by these researches in regard to the treatment of tuberculous affections are that tuberculin can be absorbed from the alimentary canal and that it can be utilised in this manner for purposes of treatment, but whether this method possesses any advantages over hypodermic administration other than convenience to compensate for the greater difficulty in graduating the dose remains to be proved. With reference to vaccine treatment without opsonic determinations this has been consistently employed for years by TRUDEAU, who from his clinical studies gave smaller doses than were generally employed and obtained good results. The confirmation afforded by the work of Dr. LATHAM and his co-workers of the possibility of graduating and spacing the doses from the clinical standpoint is a useful piece of work, and the conclusions given in this paper are worthy of careful consideration and should lead to an increased use of vaccines if they are confirmed after a more extended trial. At the same time it should be remembered that these agents are not to be used without great care and discrimination, since they are potent for evil as well as for good, and that if opsonic determinations are not made the study of the temperature and the clinical conditions should be very carefully carried out.

◆

The Law Relating to Inebriates.

THE Departmental Committee recently appointed by the Home Secretary to inquire into the working of the law relating to inebriates will have the advantage of entering on its labours at a moment when the question of the duties and responsibilities of the State in connexion with the social problem of intemperance is engaging in a special manner the attention of the public. In referring to this circumstance as an advantage we use the word advisedly, for though it may be open to doubt whether the turmoil of party politics contributes very largely to the advancement of truth (whether, for instance—to give the general principle its particular application—the acrimonious debates on the Licensing Bill, which at present bulk so largely in the columns of the daily press, are likely to determine with scientific exactitude the relation between a plethora of public-houses and an excessive consumption of liquor), nevertheless, it is highly probable that the interest awakened by controversy regarding the more polemical aspects of a question may exercise a favourable influence on the discussion of other aspects of the same problem which do not make so strong an appeal to partisan feeling. In relation to the controversial issues of the liquor problem the question of the proper treatment of habitual drunkards is in the fortunate position of lying outside the sphere of party politics and should have no tendency to inflame the prejudices either of the teetotaler or of the zealous advocate of the rights of "the trade." And it may therefore be reasonably hoped that the heat engendered by the clash of opinion on the points where the views of these two classes are strictly at variance may be available as driving energy for reform in this particular direction where they are in agreement.

While a virtual consensus of opinion may safely be taken for granted as regards the fundamental principle that habitual drunkards require in their own interest and in that of their fellows to be subjected to special control, the translating of this principle into effective legislation raises questions of detail which present difficulty in their solution.

one is ready for occupation, and that at the same time funds must be found to pay off a debt which has increased by £7700 owing to the working expenses of the last two years. And upon such a striking text Mr. Whitelaw Reid delivered an admirable little sermon concerning the oft-heard proposal to municipalise the insufficiently endowed hospitals, the gist of which may be summed up in a few of its own words. He believed that the task ahead of King's College Hospital would be accomplished, but the question of how it was to be done was of almost supreme importance, and it made him ask his audience, "Should it be done spontaneously and sympathetically as they and their fathers had done it in the past, or should the relief of the helpless sick and suffering be regarded henceforth as a mere burden on property, like drainage or paving?" Mr. Reid went on to proclaim his faith in the voluntary upkeep of hospitals as opposed to their municipal support under a scheme of assessment, largely because help tendered personally and spontaneously to the indigent sick on the ground of a common humanity was a far more ennobling influence in the community than the necessarily cold officialdom of civic control which must of necessity follow civic support. Few unprejudiced persons who have seen the relative human sympathy which qualifies the relief afforded by hospital and workhouse respectively will feel any hesitation in subscribing to that opinion. But if some should object that the weight of the argument lies in sentiment alone, and must give way before the harder necessity of business considerations, we would answer that even if by a widely-levied rate all our general hospitals could be placed to-morrow on a sound financial footing, yet their independence from future anxiety in that respect would be only gained by the sacrifice of an independence far more valuable to the interests of the poor whom they exist to serve. The present method of hospital government by boards consisting of private and charitable individuals has the broad result of securing that appointments to the medical staffs shall be made on professional and personal merit. It is on the skill and conduct of the medical staff that a hospital's good name ultimately rests. Here and there perhaps an appointment may be made which has some suspicion of nepotism, but in the vast majority of cases the reputations of our hospitals are in the keeping of men well worthy of their high responsibility, because they gain office through merit and not by fear or favour. If municipal boards are to replace the present disinterested councils in the control of the general hospitals past experience of "local administration" in certain other matters compels us to think that the purity of the principles at present governing election to hospital staff appointments must suffer degradation, with a consequent irretrievable loss to the interests of the suffering poor and of the progress of scientific medicine. The problem is an urgent one and affects every one of our great hospitals. Next week another hospital, St. Mary's, is making a supreme effort to obtain a fund of money large enough to equip and to open a much-needed wing, and we believe the appeal will not be made in vain. Private philanthropy is the foundation-stone of the English hospital system, which we trust will ever remain on that foundation. If our hospital system be placed on a bottom of compulsory support by the ratepayers its whole fabric can hardly escape deterioration in the process.

MEDICINE IN THE ATHARVA-VEDA.

IN the late Professor Whitney's translation of the Atharva-Veda, which under the distinguished editorship of Professor Lanman has in recent years been issued by the authorities of Harvard, there are many passages of interest to the student of primitive medical history. The Atharva-Veda was the latest of the Vedic collections to be recognised as part of the sacred canon. It is, in fact, the youngest of the Vedas and as such it differs considerably from the older literature of the Rik period. "The hymns of the Rik reflect chiefly the religious notions of the more intelligent and educated minority." The Atharva-Veda, on the other hand, reflects the notions of a conquered majority. It is full of spells and incantations, and medicine in it appears as a system of magic while illnesses are the work of evil spirits. The use of amulets is everywhere referred to and prescriptions take the form of poetical prayers against various ailments. "Release thou him from headache and from cough—whoever hath entered each joint of him; the blast that is cloud-born and wind-born, let it attach itself to forest-trees and mountains." So runs a mystic prayer to ward off the sicknesses resulting from lightning. Many of the prayers are malevolent and are directed against the virility or fecundity of hated rivals. But now and then we meet with a strain of lofty poetry, as in the hymn in Book X. of the Atharva-Veda on "The wonderful structure of man," which suggests the "Book of Job":—

> How many gods, and which were they, who gathered the breast, the neck-bones of man? How many gathered the shoulder-bones, how many the ribs?
>
> Who brought together his two arms, saying "he must perform heroism"? What god then set on his two shoulders upon his body?
>
> Who bored out the seven apertures in his head—these ears, the nostrils, the eyes, the mouth, in the might of whose conquest in many places quadrupeds and bipeds go their way.
>
> Numerous things dear and not dear, sleep, oppressions and wearinesses, delights and pleasures—from where does formidable man bring them?

The next question would almost suggest a knowledge of the circulation of the blood:—

> Who disposed in him waters, moving apart, much moving, produced for river-running, strong, ruddy, red, dark, and turbid, upward, downward, crosswise in man?
>
> Who put about him clothing? Who prepared his lifetime? Who extended to him strength?

The list of these questions in the hymn is a long one: together they prove that the earliest Aryans could reverence the human body in a spirit entirely noble and free from superstition.

THE NATIONAL ASSOCIATION FOR THE FEEBLE-MINDED.

Lady Frederick Brudenell-Bruce presided at the annual meeting of the National Association for the Feeble-minded which was held in Lord Brassey's Indian Room on May 8th. In her introductory address she appealed for more money and more workers, some £8000 being required to equip thoroughly a farm colony of about 100 acres in extent which is to afford an agricultural farm for boys, a flower farm for girls, and a school for the children. She announced that H.R.H. Princess Christian of Schleswig-Holstein has graciously given her name to the fund which is to be raised with this object. Lady Brudenell-Bruce dwelt upon the national character of the association's work and the necessity for the segregation of weak-minded persons in the interests of the race. Last year 652 cases had been inquired into in detail and assisted, which represented an enormous amount of individual work. Mr. Anthony Hope Hawkins fully endorsed the appeal from the chair and dwelt upon the necessity of personal interest to supplement public assistance in the treatment of these cases which he well described as "unfortunates, subnormal in intellect and will." Sir T. Clifford Allbutt presented the national issue very plainly to his audience, showing that the time had come for the question of propagation by degenerates to be faced resolutely, however difficult the problem seemed. Imbecile women especially must be protected against their own weakness and the machinations of others, as was proved by the large illegitimate families which are not uncommonly produced by such unfortunates; he maintained that the only way in which they could be protected without intolerable interference with parental control was by the coöperation of the parents, the State, and such associations as that for which he was pleading. The establishment of a Ministry of of delirium tremens, and yet at no stage of his career find himself under control as a dangerous inebriate. The natural result of this system, as may be seen in the annual reports of the Inspector of Inebriate Reformatories, has been that of the small number of persons committed to such institutions since the Act came into force—considerably under 3000 in all—a large majority were persons of congenitally weak mind, in whom, as is well known, inebriety, or what passes as such, is merely one, and except perhaps to a policeman by no means a specially important, manifestation of a general defect of development in intellect and will. The cases which belong to the vastly larger and more important category of the alcoholic, those in which the diseased condition is the consequence and not the cause of alcoholic excess, and may be removed by the arrest of such excess, have been practically excluded from the operation of the Act. This result is not only regrettable as tending to discredit the principle of reformatory detention but it also helps to create a false conception of inebriety which is likely to prove a serious obstacle to the extension of this method of treatment to curable cases. Even in official publications it is possible to detect some traces of this influence and to discover a certain disposition to assume that the characteristics common to the group of half-witted prostitutes who form the bulk of the inmates of the inebriate reformatories are the hallmark of an inebriate diathesis which is an indispensable condition to the development of alcoholic habits. This is a fallacy which the inquiries of the Departmental Committee should have little difficulty in exploding, and it may be questioned whether at the present moment it could render any greater service to the cause of the rational treatment of alcoholism than by clarifying ideas on this fundamental matter and by establishing a definition of inebriety based on the observations of the physician rather than on the intuitions of the policeman.

◆

The Declining Birth-rate in the United Kingdom.

THE variations in the rate of decline in the recorded birth-rates in the three divisions of the United Kingdom, and more especially the very slight, if any, decline that has occurred in Ireland, have scarcely received the notice which they deserve. The last issued annual report of the Registrar-General for England, relating to the year 1906, contains some useful summary tables showing the marriage-, birth-, and death-rates in the several parts of the United Kingdom and in the principal British colonies during the 25 years 1881–1905. These tables afford the means for calculating and comparing the proportional decline in the birth-rates during this period in England and Wales, Scotland, and Ireland. In the whole of the United Kingdom the annual birth-rate, which averaged 32·1 per 1000 of the population during the five years 1881–85, had fallen to 27·7 in the five years 1901–05, showing a decline of 13·9 per cent. in the 20 years. In England and Wales the decrease during the same period was from 33·5 to 28·1 per 1000, the decline being equal to 16·2 per cent.; while in Scotland the birth-rate declined in the same period from 33·3 to 28·9 per 1000, equal to a decrease of 13·0 per cent. In Ireland, however, where from causes which call for further notice the birth-rate is constantly much lower than in England and Wales or in Scotland, the rate per 1000, which was equal to 23·9 in 1881–85, only declined to 23·2 in 1901–05; the decrease did not therefore exceed 3·0 per cent. It should be borne in mind that the birth-rates noted above are all what are now correctly described as crude birth-rates, no account being taken in their calculation of the changed age-constitution of the populations resulting from the recent continuous decline in the birth-rates. Tables given in the Registrar-General's report show that the decline in the birth-rate in England and Wales, corrected for this change of age-constitution, by its calculation on the estimated female population aged 15–45 years, living at the different periods, has really been considerably greater than that derived from a comparison of the crude uncorrected birth-rates. This is probably also the case as regards Scotland, where the rate of decline shown by the crude rates differs but slightly from that in England and Wales. As regards Ireland, however, it should be remembered that the estimated total population actually declined by considerably more than half a million during the period 1883–1903 and that the emigrants mainly consisted of men in their prime and women of child-bearing ages. It is, therefore, more than probable that if the birth-rate in Ireland were corrected for the obvious changes in the age-constitution of the population resulting from this emigration, the slight decline shown by the crude birth-rates would more than disappear. The practical absence of decline in the Irish birth-rate is also noticeable if we compare the recorded birth-rates in London and Dublin in recent years. The birth-rate in London in 1867 was equal to 36·5 per 1000 and since that date has, with occasional slight exceptions, steadily declined and during last year fell so low as 25·7, the lowest London rate on record; the decrease in the London birth-rate during the 40 years has thus been equal to 29·6 per cent. The mean annual uncorrected birth-rate in London during the five years 1881–85 was 32·9 per 1000 but had declined 20 years later (1901–05) to 26·9, showing a decrease equal to 19·5 per cent. In Dublin, on the other hand, the annual crude birth-rate was equal to 26·9 per 1000 in the five years 1866–70 and had actually increased to 29·1 in the most recent five years 1903–07. The Dublin birth-rate has, moreover, been practically stationary during the period 1883–1907, the mean rate being 28·9 in the five years 1881–85, and 29·1 in the five years 1903–07. There appears, therefore, to be no trustworthy evidence of any real decline in the Irish birth-rate, and certainly of no decline similar to that shown by the recorded birth-rates in England and Wales and Scotland, a fact which seems to call for further explanation.

Annotations.

"Ne quid nimis."

THE SUPPORT OF HOSPITALS BY THE VOLUNTARY SYSTEM.

AT the annual festival dinner in aid of King's College Hospital the American Ambassador, who was in the chair, presented the supporters of the hospital with this problem: that £106,000 must be collected by the time the new building in South London is completed in addition to the £194,000 already obtained by voluntary subscription, that the current expenses of the present hospital must be met until the new etiological factor, while in others it plays a secondary part. After a careful consideration of his own results and a comparison with those of other observers, Dr. Freund is convinced that this organism is the direct cause of certain forms of acute, chronic, and recurring enteritis, characterised by abdominal pain, diarrhœa, loss of weight and strength, and anæmia. Dr. David Murray Cowie of Ann Arbor and Dr. James Frederick Munson of Sonyea, N.Y., give the results of an *Experimental Study of the Action of Oil on Gastric* Acidity and Motility. They find that olive oil and cottonseed oil, when given in connexion with the usual test breakfast, decrease the gastric acidity at the end of the hour and retard the evacuation of the stomach, that the secretion of hydrochloric acid is delayed when oil precedes the meal and is unchanged when oil follows it, and that the height of secretion is lowered when oil precedes the meal and is unchanged when given afterwards. They conclude that oil is in suitable cases preferable to antacids because of its heat value, and recommend that in hyperchlorhydria it should precede the meal, that in hypochlorhydria it should follow the meal, and that its use should be avoided in stasis and persistent slow evacuation. Dr. Hugh A. Stewart of Baltimore records his observations on the Pulse and Blood Pressure Changes in Aortic Insufficiency. He confirms *Henderson's* statement that the cardiac cycle is not diphasic but triphasic, consisting of systole, *the period of* ventricular discharge; diastole, the period of ventricular relaxation and filling; and diastasis, the period of rest. From experimental investigations he finds that aortic regurgitation increases the systolic output in the dog by only a fraction of a cubic centimetre of blood and that the volume of blood which regurgitates *is negligible. The fall* of blood pressure in aortic regurgitation is due to the diminished peripheral resistance brought about by a reflex inhibition of the vasomotor centre and not *to loss* of blood by regurgitation. We wish the American Medical Association every success in this endeavour to found a periodical dealing with the scientific aspects of medicine.

PREMATURE BURIAL.

In a contemporary journal on April 23th there appeared under the following headlines, "Living Woman in a Coffin—Narrow Escape from being Buried Alive," a detailed account of an alleged circumstance calculated to strike terror into the minds of people, and especially those who are unusually receptive of the marvellous. In a later issue it was stated that there was no foundation for the report. Although premature burial cannot be denied absolutely we may say with Brouardel, "if a mistake has been made it is a popular blunder and not a medical *one*." There are many circumstances which cause death to be simulated but the phenomenon can never, at least in this country, give rise to a mistaken belief when properly examined by a qualified medical man. Apparent death, or, as it has been termed, "latent life," is occasionally observed under a variety of conditions. In hysteria, catalepsy or trance, and syncope from mental or physical shock the signs of life may be reduced to a minimum. The same occurs in many cases of so-called stillbirth and in supposed deaths from drowning. Prolonged attempts at resuscitation of bodies apparently lifeless at once exemplify the condition and indicate the knowledge that life may be distinguished from the simulacrum of death. Short of cadaveric decomposition there is no certain sign of death, much less an absolute criterion which can determine the precise moment of death. In some cases of somatic death—e.g., after decapitation—the heart, once termed "ultimum moriens," has been known to beat for many minutes. It is not our purpose to discuss here the various signs of death and their relative value but to assail what has become in some degree a popular belief that bodies may be buried alive because of the supposed inability to prove that they are dead. We say without hesitation that cases of simulated death are few, and that those in which the likeness cannot be effaced do not exist. Of the recorded instances of premature burial the vast majority are wholly devoid of foundation in fact, and the doubtful remainder are wanting in substantiation by the only evidence worthy of credence—that of a qualified medical man. In some parts of Germany what are termed funeral chambers are provided for the purpose of watching bodies in order to verify the fact of death. In some of these a bell rope is placed in the hands of the corpse, but as a distinguished authority has pithily remarked, "since the institution of these chambers no one has ever heard the bell ring." We may fittingly close these remarks with the words of Brouardel, "Let us say at once that one fact is found to be almost constantly present—viz., in the immense majority of cases the persons died without having been *seen during their* illness by a physician, and were buried without a physician having had the opportunity of verifying their death."

THE MEDICAL SOCIETY OF LONDON.

At a general meeting of the Medical *Society of London*, held at 11, Chandos-street, Cavendish-square, London, on May 11th, Mr. C. B. Lockwood was elected President and the following were elected members of the Council: Mr. Charles A. Ballance, Dr. Walter Broadbent, Mr. Edred M. Corner, Dr. Bertrand Dawson, Dr. John H. Drysdale, Mr. Harold A. T. Fairbank, Colonel Sir Joseph Fayrer, Bart., R.A.M.C., Dr. James Kingston Fowler, Mr. A. Corrie Keep, Mr. V. Warren Low, Dr. Percy J. F. Lush, Dr. Frederick S. Palmer, Dr. J. Porter Parkinson, Dr. J. J. Perkins, Dr. Frederick J. Poynton, Mr. Herbert Tilley, Dr. R. Cecil Wall, Mr. Charles Gordon Watson, Dr. F. Parkes Weber, and Dr. W. Essex Wynter.

THE QUESTIONABLE EFFICIENCY OF ATROPINE IN CHLOROFORM POISONING.

In the *Biochemical Journal* of April 16th Dr. W. Webster contributes notes on the action of atropine, hyoscyamine, hyoscine, scopolamine, duboisine, and daturine, representing the results of a research which was begun with the primary object of testing the efficiency of atropine as a restorative in poisoning by chloroform, or as a precautionary measure before its administration. Dr. Webster found as close a relationship between these substances as regards their physiological action as there is between their chemical structure, no difference being detected between them from a physiological point of view. The experiments were performed on dogs and cats and the anæsthetics employed were chloroform, ether, or the A.C.E. mixture, and in a few cases curare in addition. The investigation was restricted to the gross effects upon the heart, circulation, and respiration, and brought out several points of interest. In dogs atropine, hyoscine, hyoscyamine, scopolamine, and daturine, whether in small *or large doses*, produced a lowering of the blood pressure. Dr. Webster considers that although these drugs eliminate the tonic inhibitory action of the vagus, they have a simultaneous action on the heart substance, diminishing the output. The frequent administration of increasing doses of these drugs produces a condition of tolerance within one or two hours, enabling the animal to withstand, with comparatively slight reaction, very many times the dose which would have been fatal at the beginning of the experiment. In small doses the respiration is quickened and rendered deeper, in large doses it is often paralysed immediately. In so f as they go these experiments do not tend to encourage use of atropine in chloroform poisoning. Suprarenin, other hand, seems to be of much more, though utility. Its effect is transitory, so that as a

Health was an essential to the proper preventive treatment of such grave problems as this which the association was facing. Mr. W. H. Dickinson, M.P., gave an interesting account of the successful working of large farm colonies in America which afford varied employment and interests to their feeble-minded inmates; he laid stress upon the personal qualities required by the officers owing to the fact that a feeble-minded person was practically a child, happy as long as he received proper care and affection. Dr. Robert Jones gave the meeting those national statistics of insanity and imbecility which unhappily our readers have only too often before them, and after dwelling upon their proved consequences made a spirited appeal for the study and practice of eugenics. He supported strongly both the aims and the methods of the association, which had evoked his warm admiration. Finally, Miss Adler spoke of the important after-care work of the association, which she considered should be taken up by local authorities. We were pleased to see that many ladies evidently belonging to the leisured and influential classes were present at this meeting. When such facts are widely known as were told to them in undisguised language concerning the propagation of the unfit the nation will begin to see that the wise and sympathetic control of uncertifiable "border-line" mental cases in such settlements as this association seeks to found is demanded in the urgent interests of the nation no less than in those of the afflicted individuals themselves. As the speakers at this meeting suggested, it is personal sympathy which can alone deal with them in the best possible manner. We heartily commend the work of this association in its educational, its charitable, and its national purposes, and we trust that the money may be forthcoming to found the proposed farm colony.

RECOVERY FROM DISLOCATION OF THE NECK.

IN rare cases recovery has taken place after dislocation of the neck. In the *New York Medical Journal* of April 18th Dr. Lucien Lofton has reported the following remarkable case. A youth, aged 20 years, while adjusting a chain beneath a steam shovel was caught round the neck by it and drawn up against the floor of the machine. The left side of his head was pressed against the under surface of the shovel for several seconds. When released he fell limp to the ground and appeared to be dead to those who removed his body. Within a few seconds he showed signs of recovery. When he regained consciousness he asked for water but after repeated attempts for an hour he could not swallow it. Dr. Lofton saw him about three hours after the accident, when he was much improved. He did not complain of pain but only that his neck was sore. On being offered drink he could with great difficulty use some of the muscles of deglutition. The pulse was 58 and the respiration was 14. There was complete sensory and motor paralysis below the chin, excepting a slight movement of the right index finger, and loss of control of the sphincters. He talked intelligently and could whistle, expectorate, protrude the tongue, and make any facial contortion requested. The neck was stretched one and a half inches. The ventral arch of the atlas rested upon the odontoid process of the axis. Reduction was performed in the following manner. The patient was placed flat upon the ground. Two assistants grasped his lower limbs and two placed their hands on his chest to steady the trunk. Dr. Lofton then firmly grasped the occiput with his right hand and placed his left under the chin. By lifting the head backwards, upwards, and forwards upon the chest he replaced the atlas in its normal position. He performed each step of the manipulation deliberately and slowly. No anæsthetic was used for fear of direful results. During the reduction the patient complained of much pain, especially in the throat, and said that he felt as if he were about to choke. No immediate sensory or motor improvement was observed upon reduction but there was a desire to micturate. The neck and head were fixed in their normal position with adhesive plaster. The patient was taken home in an ambulance. When he arrived, about 11 hours after the accident, the pulse was 76 and the respiration was 19. He was placed in bed with the head elevated about eight inches. The plaster on the neck was reinforced with bandages. The temperature never rose above 99·6° F. On the fourth day the paralysis began to diminish in the left leg and right forearm. On the seventh day he could move the right foot. Gradually the use of the muscles of deglutition, the erector spinæ, the muscular system generally, and the sphincters was regained. The dorsal decubitus position was maintained for ten days. Then massage, hot sponging, and faradism were used and the patient could change his position with assistance. On the fifteenth day he contracted measles which ran the usual course. On the thirtieth day he could sit up and walk a few steps. Massage and faradism were used for five and a half months. At the end of this time the only evidence of the injury was partial atrophy of the left deltoid muscle.

THE ARCHIVES OF INTERNAL MEDICINE.

WE have received a copy of the first number of the *Archives of Internal Medicine*—a new magazine produced and published by the American Medical Association. It is to appear in monthly parts and the subscription price is $4 per annum, including postage. It is under the direction of an editorial board consisting of Dr. R. C. Cabot of Boston; Dr. George Dock of Ann Arbor, Michigan; Dr. David L. Edsall of Philadelphia; Dr. Theo. C. Janeway of New York; Dr. W. S. Thayer of Baltimore; and Dr. Joseph L. Miller of Chicago. Judged by the first number the American Medical Association is to be congratulated on its new venture. It contains five papers, the first being the Harvey Lecture delivered at the New York Academy of Medicine by Dr. Friedrich Müller of Munich on the Nervous Affections of the Heart, which is an interesting presentment of this complex subject viewed from the clinical standpoint in the light of the recent advances afforded by the experimental study by scientific physiological methods of the heart's action and its control by the central nervous system. Dr. Richard Weil of New York City contributes a short paper on the Hæmolytic Reactions of the Blood in Dogs affected with Transplantable Sarcoma. Having found in a previous investigation that hæmolytic substances could be extracted from these tumours in dogs, he now maintains as a result of his experiments that the serum of all the dogs with these tumours is distinctly more hæmolytic than that from normal dogs, and further that the corpuscles of the animals with tumours are more refractory to the destructive effects of the hæmolytic serum than those of normal dogs. He draws attention to the bearing which these results may prove to possess in regard to the anæmia associated with new growths. Dr. Hugo A. Freund of Detroit contributes an important paper with the title "Trichomonas Hominis Intestinalis: a Study of its Biology and Pathogenicity." He points out that American and English writers have not attached sufficient importance to this organism. He describes its morphology in considerable detail and gives some good plates in illustration. So far it has been found impossible to cultivate this organism. Dr. Freund has had the opportunity of showing the clinical course and symptoms of ten cases in which these organisms were found in the fæces, and of these cases he gives details. The trichomonad is found in a variety of pathological conditions, in some of which it would appear to be an etiological factor, while in others it plays a secondary part. After a careful consideration of his own results and a comparison with those of other observers, Dr. Freund is convinced that this organism is the direct cause of certain forms of acute, chronic, and recurring enteritis, characterised by abdominal pain, diarrhœa, loss of weight and strength, and anæmia. Dr. David Murray Cowie of Ann Arbor and Dr. James Frederick Munson of Sonyea, N.Y., give the results of an Experimental Study of the Action of Oil on Gastric Acidity and Motility. They find that olive oil and cottonseed oil, when given in connexion with the usual test breakfast, decrease the gastric acidity at the end of the hour and retard the evacuation of the stomach, that the secretion of hydrochloric acid is delayed when oil precedes the meal and is unchanged when oil follows it, and that the height of secretion is lowered when oil precedes the meal and is unchanged when given afterwards. They conclude that oil is in suitable cases preferable to antacids because of its heat value, and recommend that in hyperchlorhydria it should precede the meal, that in hypochlorhydria it should follow the meal, and that its use should be avoided in stasis and persistent slow evacuation. Dr. Hugh A. Stewart of Baltimore records his observations on the Pulse and Blood Pressure Changes in Aortic Insufficiency. He confirms Henderson's statement that the cardiac cycle is not diphasic but triphasic, consisting of systole, the period of ventricular discharge; diastole, the period of ventricular relaxation and filling; and diastasis, the period of rest. From experimental investigations he finds that aortic regurgitation increases the systolic output in the dog by only a fraction of a cubic centimetre of blood and that the volume of blood which regurgitates is negligible. The fall of blood pressure in aortic regurgitation is due to the diminished peripheral resistance brought about by a reflex inhibition of the vasomotor centre and not to loss of blood by regurgitation. We wish the American Medical Association every success in this endeavour to found a periodical dealing with the scientific aspects of medicine.

PREMATURE BURIAL.

IN a contemporary journal on April 28th there appeared under the following headlines, "Living Woman in a Coffin—Narrow Escape from being Buried Alive," a detailed account of an alleged circumstance calculated to strike terror into the minds of people, and especially those who are unusually receptive of the marvellous. In a later issue it was stated that there was no foundation for the report. Although premature burial cannot be denied absolutely we may say with Brouardel, "if a mistake has been made it is a popular blunder and not a medical one." There are many circumstances which cause death to be simulated but the phenomenon can never, at least in this country, give rise to a mistaken belief when properly examined by a qualified medical man. Apparent death, or, as it has been termed, "latent life," is occasionally observed under a variety of conditions. In hysteria, catalepsy or trance, and syncope from mental or physical shock the signs of life may be reduced to a minimum. The same occurs in many cases of so-called stillbirth and in supposed deaths from drowning. Prolonged attempts at resuscitation of bodies apparently lifeless at once exemplify the condition and indicate the knowledge that life may be distinguished from the simulacrum of death. Short of cadaveric decomposition there is no certain sign of death, much less an absolute criterion which can determine the precise moment of death. In some cases of somatic death—e.g., after decapitation—the heart, once termed "ultimum moriens," has been known to beat for many minutes. It is not our purpose to discuss here the various signs of death and their relative value but to assail what has become in some degree a popular belief that bodies may be buried alive because of the supposed inability to prove that they are dead. We say without hesitation that cases of simulated death are few, and that those in which the likeness cannot be effaced do not exist. Of the recorded instances of premature burial the vast majority are wholly devoid of foundation in fact, and the doubtful remainder are wanting in substantiation by the only evidence worthy of credence—that of a qualified medical man. In some parts of Germany what are termed funeral chambers are provided for the purpose of watching bodies in order to verify the fact of death. SCANDINAVIAN WINTER HEALTH STATIONS.

(BY A SPECIAL COMMISSIONER.)

III.[1]

HEALTH CENTRES IN NORWAY.

NORWAY has a great future before it. It is a land possessed of immense possibilities. Its coast line is of great extent. Its waterfalls are a readily secured means of power. Its rivers, its lakes, its fjords, and its easy access to the sea afford unrivalled facilities for transit. Its people are well-educated, industrious, ambitious, patriotic, yet simple, hospitable, and courteous. Its laws, its schools, and its public institutions afford models for other less progressive countries. Its King and Queen are in close touch with, and manifest a real sympathy in, the aspirations of the people and are justly respected and rightly popular. But with all these endowments of nature and advantages of character and government, Norway is a comparatively poor and sparsely populated land. Its present population is less than two and a quarter millions. It is necessary to bear all these points in mind when considering, at least from the English standpoint, the possibilities and advantages of Norway as a land for the health seeker and the sportsman. The very simplicity which comes from a lack of elaboration and artificiality has its advantages. Among these must be mentioned as of special importance the very reasonable and, one might almost say, cheap rates prevailing in some of the best establishments well adapted to the needs of English visitors and also at sanatoriums for consumptives to which English patients might well be sent. The high prices existing in many British and foreign sanatoriums and health resorts are prohibitive for many middle-class patients who might be able to meet the very moderate charges of certain of the Norwegian establishments.

In many parts of Norway those responsible for the management of excellent health stations have hardly realised their possibilities for development. Their outlook needs to be less restricted. Steps must be taken to make Norwegian resorts known to English physicians if they would have English patients. In only too many instances prospectuses are printed only in Norwegian and German. This is a very short-sighted policy, hardly to have been expected of the Norwegian who is taught English in all his schools. Once in Norway the language difficulty hardly exists, for in almost every establishment English is spoken. Nearly all the many medical men with whom your Commissioner consulted spoke more or less excellent English. If Norway desires England and the rest of Europe to recognise her land as a centre to which health seekers may resort, she will have to follow the example of Switzerland, Italy, France, and Austria, and other countries and advertise.

The main lines of railway in Norway now belong to the State. A wise progressive policy on the part of those who govern the means of transit, which at present although comfortable are nevertheless infrequent and slow, will do much to attract visitors and to encourage travelling.

As matters are at present, English visitors during the winter will probably in most cases prefer to be at a resort where winter sports may be enjoyed, which is easy of access and which, moreover, is not far removed from a town centre. For such the health resorts in the immediate neighbourhood of Christiania should be given first place. The claims of Trondhjem should also be considered. Some will doubtless prefer the inland and upland health and sports centres chiefly situated in the eastern districts of Norway. It is well to remember that the telephone affords a means of linking up the seemingly most isolated parts of the country. I propose to describe the chief features of some of the health resorts most likely to appeal to English visitors.

HEALTH STATIONS NEAR CHRISTIANIA.

The best known, most accessible, largest, and most elaborately equipped of Norwegian health establishments are to be found on the southern spur of the forest-covered mountain range of Nordmarken, some seven kilometres or an hour's journey by electric car from the centre of Christiania. Here, on the northern side of the city, at an altitude of from 1100 to 1480 feet, several so-called "sanatoriums" are situated on dry, rocky soil, surrounded by thick forests of pine and fir, admirably sheltered from the cold winds coming from the north, open to the south, with abundance of sun, and unrivalled views over Christiania and its beautiful fjord and away to the rolling mountains of Telemarken and the southern and south-western districts of Norway.[2] The situation is almost ideal. Here within easy reach of all the privileges and conveniences of the country's capital and university centre, and with all the attractions of a city having a monarch's residence, a national theatre, educational and other institutions of the best, and a water and rail service to all parts of Europe, are placed health and sports stations which may well compare with the best in any part of the world.

The natural resources are many and the most has been made of them. The pure mountain and forest air, the sheltered walks, the subalpine climate, the freedom from fogs, the abundance of sunlight, and the protection from winds, combine to afford health-giving and renewing forces eminently suited to the requirements of the overworked and mentally fagged patients debilitated by disease, convalescents of all kinds, subjects of insomnia and other nervous ailments and sufferers from asthma and other chronic affections. Tuberculous and all cases in any way of an infectious nature, needless to say, are not welcomed.

During the winter the residents of Christiania following the example of King Haakon and Queen Maud resort in ever-increasing numbers to this delightful district to engage in the fascinating sports of tobogganing, ski-ing, and the like. The sanatoriums are open all the year round but their chief attractions, at least for many, exist during the winter months. Brief reference can only be made to the chief establishments. In addition to those mentioned there are some few *pensions* to which Norwegians resort and many private villas have now been built for permanent residents.

Holmenkollen Sanatorium (Fig. 1) was established in 1894 through the enterprise of Dr. I. C. Holm. It was designed by the architect, B. Lange. It now consists of two buildings containing 70 and 100 beds respectively. The main front which faces due south contains 26 spacious apartments. Along the north side runs a broad well-lighted corridor. At the west end in a large wing are placed the dining and drawing rooms, billiard room, and consulting rooms. The picturesque entrance hall and lounge are artistic and comfortable. Practically all the rooms are heated by a central low-pressure heating apparatus and lighted by electricity. The new annexe, designed by the architect O. Sverre, lies to the north-west of the main block and contains 36 rooms, of which 20 face south. There is an excellent new bath house where all forms of baths may be obtained. Provision is also made for the conduct of electrical treatment and massage under proper medical supervision. Dr. Olaf Bergh is the present resident physician. Inclusive terms vary from £8 to £14 per month of four weeks. Adjacent to the sanatorium is the celebrated Tourist Hotel, erected in 1896 in characteristic old Norse style and having its chief rooms adorned with historical and mythological scenes by Munthe and other Norwegian artists. Close by is the famous *Sportstue*, much frequented by sportsmen.

Voksenkollen Sanatorium, opened in 1900, is a thoroughly modern establishment erected at a higher elevation, also through the efforts of Dr. Holm, who acts as the resident director and physician and to whom your Commissioner is indebted for much kindness and information. The general characters of the building are shown in Fig. 2. The sanatorium is excellently situated and is in every way adapted to its purpose and may well claim the premier position among establishments of this class in Norway. It is a favourite resort of the King and Queen of Norway. There are 100 artistically furnished rooms, fitted with electric light, comfortably heated, well ventilated, and having modern sanitary appliances. The dining and drawing rooms are large and charming apartments and the central lounge, hall, staircase, and reading and smoking rooms, all richly ornamented in Norwegian style, are very attractive features. Dr. Holm has equipped his establishment with education. In proof of this they may mention, that no addition has been made for nearly a century, to the fee required in obtaining a diploma (which amounts to 6*l.* 5*s.*); so that were the proposed stamp-duty imposed, the expense of obtaining this certificate, already it is believed as large as those applying for it can afford, would be nearly trebled.

---

[1] Nos. I. and II. were published in THE LANCET of April 25th (p. 1235) and May 2nd (p. 1305), 1908, respectively.

[2] In the illustrations of the various establishments the buildings are not represented in any uniform scale, but their respective sizes can be gauged fairly accurately by observing the roof lines and the number of windows in the façades. No uniformity of scale was possible if any idea of the environing landscape was to be given.

In these circumstances, this tax could not fail to be most oppressive to those applying for surgical diplomas.

Your petitioners have also to represent, that a diploma in surgery, although at present generally taken by those educated at the different medical and surgical schools, is a mere certificate of qualification, not conferring any privilege, and is not required by law to be possessed by those who practise surgery or medicine in the greater part of the United Kingdom. In these circumstances, there seems great reason to fear, that the increased expense will absolutely prevent a large proportion of medical and surgical students from taking a diploma, and they will thus be deprived of the motive to go through the full course of education which they at present follow. In this way the interests of the community will be materially injured by the diminution of the number of properly qualified practitioners, and by the increase of the already-too-great number of the ill-educated and irregular; and the efforts which have been made, and are now making, to improve the education of surgeons, will be materially counteracted and impeded.

In the opinion of your petitioners, the proposed duty will operate as a tax for the prevention of the improvement and proper qualification of practitioners.

Your petitioners conceive, that even were the number of diplomas annually granted maintained at its present rate, the amount of the tax would be of little importance to the revenue; and they are satisfied, that the diminution which it is likely to occasion, would render it even less productive than is anticipated.

Your petitioners also strongly feel, that the proposed tax, by lessening the number of diplomas, would materially diminish their funds; which they have hitherto applied in promoting medical and surgical science, by the purchase and formation of extensive and valuable collections of anatomical and pathological preparations, and would involve them in great difficulties in the completion of the undertaking they have entered upon, of building suitable accommodation for rendering these preparations useful to the medical and surgical school of Edinburgh—a work which they will not be able to complete, even by the expenditure of their whole present funds, and which they commenced in the belief of the continuance of their present annual income.

Your petitioners therefore earnestly hope, that your honourable House will take the above statement into your serious consideration, and that you may be induced to abstain from sanctioning a measure, which will not, in their opinion, produce any good effect, and which they cannot but regard, for the reasons they have stated, as very oppressive to those engaged in the study of medicine and surgery—as detrimental to the improvement of medical and surgical education, and therefore injurious to the community—and as prejudicial to the interests of your petitioners.

May it therefore please your honourable House to take the above statement into consideration; and to grant your petitioners such relief in the premises as to your honourable House shall seem meet."

THE ROYAL SOCIETY.

THE conversazione of the Royal Society was held on May 13th, and though the exhibits, as a rule, were rather physical than biological, yet there were various items of interest connected with medicine having a distinct bearing upon the subject. First of all was the exhibit of Dr. E. F. Bashford on behalf of the executive committee of the Imperial Cancer Research Fund, dealing with cancer as a manifestation of cell life throughout the vertebrates. In these exhibits it was demonstrated that every animal appears to have its own cancer and that, for instance, the cancerous cells of mice cannot be propagated in rats or *vice versâ*. Another subject demonstrated was that of protection against the experimental transmission of cancer, from which it appeared that the experimentally protected animal does not supply the scaffolding of supporting tissues and vessels without which implanted cancerous tissues cannot grow into a tumour. Another very interesting exhibit was that of Mr. J. W. Gordon and Mr. H. Fletcher Moulton of a new object glass for high-power magnification. It was designed upon the principle already made known by Mr. Gordon of an oscillating screen which was described in our issue of Jan. 13th, 1906, p. 206. In the present instrument the oscillating screens had been done away with, as it had been found that the necessity for keeping the screen in motion gave rise to inconveniences and the screen now consists of a very fine deposit of precipitated sulphate of barium placed on the vertex of the front lens of the objective combination. A mirror pierced with a small central aperture, through which an image-forming beam of light can reach this screen, is formed by depositing silver on that surface of the front lens which would be its front surface were the objective used as a dry objective. In front of the mirror so deposited is placed a spherical lens, having its centre of curvature situated on the sulphate of barium screen, so that focussed rays passing through this front surface of the lens may pass without refraction. A demonstration was given of anthrax bacilli magnified to 8000 diameters and having perfect clearness of definition.

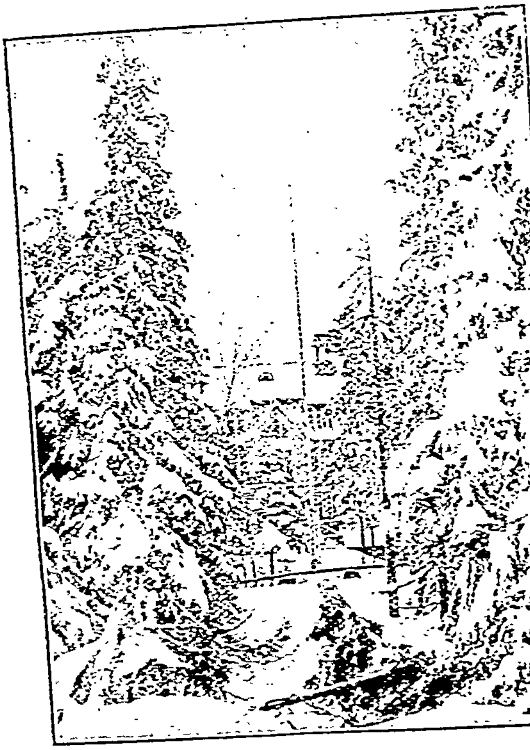
Mr. J. E. Barnard showed his mercury vapour lamps for microscopic illumination which when used in combination with an absorbent colour-screen may be made to transmit only monochromatic light. The Marine Biological Association of the United Kingdom had a very interesting exhibit of living marine fauna from the neighbourhood of Plymouth, and among other notable exhibits were Mr. Joseph Gould's uniformly symmetrical twin elliptic pendulum and Mr. Benham's method for getting twin elliptic figures available for a stereoscope. Messrs. Johnson, Matthey, and Co., Limited, showed a variety of chemical apparatus such as flasks, crucibles, and the like in transparent fused silica, and Professor J. Symington, F.R.S., together with Dr. J. C. Rankin, showed a magnificent series of skiagrams illustrating the development of teeth in man. Great interest was shown in Professor W. B. Bottomley's exhibit of the bacterial treatment of non-leguminous plants such as barley, turnips, radishes, and tomatoes. The effect of bacterial cultures used is not merely to make the plant tissues absorb nitrates or nitrogen but to bridge the gap between the nitrate and an amide, so that, like Mother Carey in the Water Babies, the bacteria make plants make themselves.

FIRE AT GORDON COLLEGE, KHARTOUM.—We regret to learn that an alarming fire broke out in the Wellcome Research Laboratories, Gordon Memorial College, Khartoum, on May 11th, and that before it was got under control considerable damage was done.

THE FIRST INTERNATIONAL FIRST AID AND LIFE-SAVING CONGRESS.—In THE LANCET of April 11th we published a preliminary abstract of the arrangements which had then been made for the First International First-Aid and Life-Saving Congress to be held at Frankfort-on-the-Main from June 9th to 13th. The proceedings will be conducted in a number of sections, two of which will deal with medical first aid in cases of accident and the instruction of non-professionals in first aid. The other sections will be devoted to ambulance work under a variety of conditions—namely, in towns, in the country, on railways, at sea and on inland waters, in mines, at fires, and so on. Any resident in the United Kingdom who is interested in the subject and is desirous of attending the Congress should communicate immediately with the honorary secretary of the English committee, Mr. S. Osborn, F.R.C.S. Eng., Maisonnette, Datchet, near Windsor. The following are the five principal routes from London to Frankfort, the fares being in each case appended: (1) Harwich, Hook of Holland, Rotterdam, Cologne (first-class, single £3 10*s.* 3*d.*, return £5 9*s.* 10*d.*; second-class, single £2 6*s.*, return £3 15*s.* 6*d.*); (2) Harwich, Antwerp, Cologne (first-class, single £3 5*s.*, return £4 19*s.* 7*d.*; second-class, single £2 0*s.* 8*d.*, return £3 7*s.* 4*d.*); (3) Queenborough, Flushing, Cologne (same fares as by Harwich and Hook of Holland route); (4) Dover, Calais, Brussels, Cologne (first-class, single £4 4*s.* 5*d.*, return £7 0*s.* 11*d.*; second-class, single £2 18*s.* 6*d.*, return £5 2*s.* 2*d.*); and (5) Dover, Ostend, Brussels, Cologne (first-class, single £3 14*s.* 2*d.*, return £6 3*s.* 2*d.*; second-class, single £2 11*s.* 8*d.*, return £4 9*s.*). Mr. Osborn will send on application a list of 20 Frankfort hotels at which the charges for a bedroom without breakfast vary from 2 marks 50 pfennig to 4 marks per day.

all modern means for effective treatment. The baths are good and there is an installation for electrical and light treatment. A large and airy gymnasium provides for the exercise of all forms of physical treatment. The immediate environs of the sanatorium are particularly delightful. The terms vary from kr. 168.00 to kr. 250.00 per month corresponding to kr. 6.00 to kr. 9.00 per diem, prices which are considerably less than would prevail in an establishment of the same kind in England.[3]

FIG. 3.



Anne Kure's Hotel, near Christiania.

Anne Kure's Hotel (Fig. 3) is a less pretentious but thoroughly comfortable establishment, situated between the above-mentioned sanatoriums. It is under the personal management of Miss Anne Kure and in all respects not only appears excellently conducted but is highly spoken of by Norwegian people as a peculiarly quiet and restful retreat. Its prices are certainly most reasonable, ranging from kr. 4.50 to kr. 7 per day.

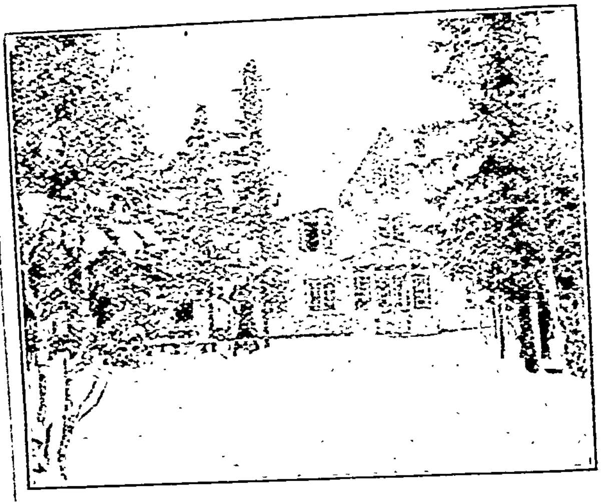
The *Pensionatet Voksenkollen Hospits* is a simple, well-conducted establishment much frequented by Norwegians, where the tariff is as low as kr. 2.50 per day.

A NORTHERN WINTER RESORT.

Trondhjem, the cathedral and coronation city of the North, is an exceedingly interesting centre.[4] Although Trondhjem can be reached directly by steamers from Newcastle and Hull, most visitors in the winter will doubtless prefer to travel by rail from Christiania, and by the night service comfortable sleeping arrangements are provided. The excellent provision for hot meals at set times at definite halting-places robs a journey in Norway of one of the chief disadvantages of long-distance travel. The only legitimate complaint that can be brought against the railway carriages is that they are almost invariably overheated. The traveller may, however, do much to regulate the temperature to his liking.

Medical men visiting Trondhjem should not fail to visit the leper hospital on the outskirts of the town. It affords one of the most pathetic sights to be seen in Europe. The eldest patient there examined by your Commissioner was said to be 84 years of age and had been there since 1862. The youngest inmate was a little girl aged three years. The only other leper hospital now existing in Norway is at Bergen.

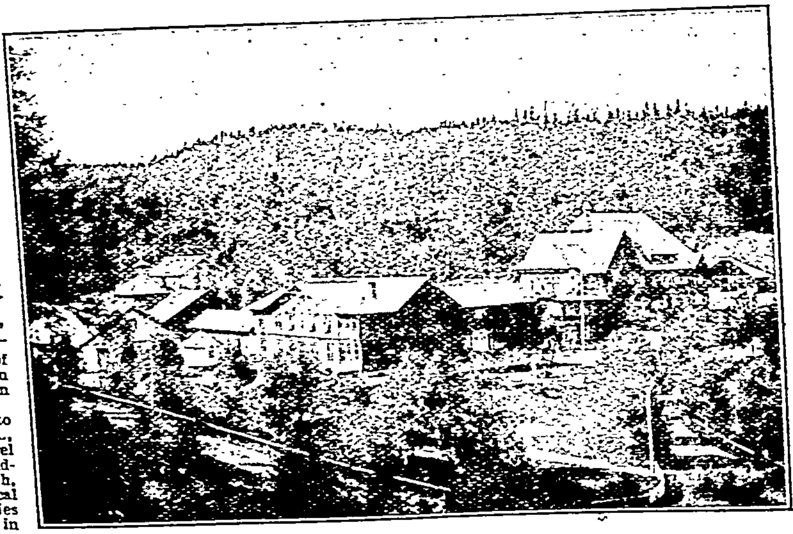
FIG. 4.



Tofte Sanatorium, Gudbrandsdal.

The chief health resort near Trondhjem is at Fjeldsæter, five miles from the city at an altitude of 1200 feet. Here at the Fjeldsæter Tourist Hotel on Graakall Hill comfortable quarters may be obtained in picturesque old Norwegian style. There are excellent opportunities for reindeer-driving, ski-ing, and other forms of winter sports, and here occurs the celebrated sports meeting where athletes from all over the country congregate and compete.

FIG. 5.



Tomaasen's Sanatorium, Valdres.

---

[3] A well-illustrated booklet descriptive of Voksenkollen Sanatorium and printed in good English will be sent to any physician applying to Dr. Holm.

[4] Visitors to Trondhjem would do well to communicate with Mr. Robert Millar, B.A., the secretary of the Trondhjem Travel Society (Turisttrafikforeningen i Trondhjem). A periodical printed in English, "The Tourist News," affords much local information. The Scandinavian Fisheries Exhibition is to be held in Trondhjem in July and August next, and should attract many English summer visitors.

of these, 27 resulted from measles, 19 from whooping-cough, 13 from diarrhœa, seven from "fever," six from diphtheria, and five from scarlet fever, but not one from small-pox. These 77 deaths were equal to an annual rate of 2·2 per 1000, the mean rate from the same diseases in the 76 English towns during the same week not exceeding 1·1. The 27 fatal cases of measles in the Scotch towns exceeded the number in the previous week by three, and included 16 in Glasgow, four in Edinburgh, four in Aberdeen, and three in Greenock. The deaths from whooping-cough, which had been 12 and 20 in the two preceding weeks, were 19 in the week under notice, of which seven occurred in Glasgow, four in Edinburgh, and two each in Dundee, Aberdeen, and Paisley. The 13 deaths attributed to diarrhœa corresponded with the number in the previous week, including four in Glasgow, three in Edinburgh, three in Aberdeen, and two in Dundee. The seven deaths referred to "fever" exceeded the number in the previous week by two, and were all certified as due to cerebro-spinal meningitis; five occurred in Glasgow and two in Edinburgh. Five of the six fatal cases of diphtheria were returned in Glasgow; and the five deaths from scarlet fever included three in Glasgow and two in Leith. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 113 and 107 in the two preceding weeks, rose again to 119 in the week under notice, and exceeded the number returned in the corresponding week of last year by 11. The causes of 16, or 2·5 per cent., of the deaths in these eight towns during the week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death in the same week did not exceed 1·3 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 21·1 and 21·9 per 1000 in the two preceding weeks, further rose to 25·0 in the week ending May 9th. During the first six weeks of the current quarter the death-rate in Dublin averaged 23·3 per 1000; the mean rate during the same period did not exceed 15·2 in London and 15·9 in Edinburgh. The 189 deaths of Dublin residents registered in the week under notice showed a further increase of 23 upon the numbers returned in recent weeks, and included eight which were referred to the principal epidemic diseases; they were fewer by two than those in the previous week. These eight deaths were equal to an annual rate of 1·1 per 1000, the rate during the week from the same diseases being 1·0 in London and 1·9 in Edinburgh. Of the eight deaths from epidemic diseases in Dublin, three resulted from diphtheria, two from measles, and one each from scarlet fever, whooping-cough, and "fever," but not one from diarrhœa or small-pox. The five fatal cases of diphtheria registered during the fortnight ending May 9th were the first recorded in Dublin since the middle of March. The 189 deaths from all causes in the city during the week included 37 of infants under one year of age and 56 of persons aged upwards of 60 years; both these numbers showed a further increase upon those returned in recent weeks. 13 inquest cases and nine deaths from violence were registered, and 70, or 37·0 per cent., of the deaths occurred in public institutions. The causes of ten, or 5·3 per cent., of the deaths registered in the city during the week under notice were not certified; the causes of all but two of the 1273 deaths in London last week were duly certified, as were the causes of all the 104 deaths in Edinburgh.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Inspector-General of Hospitals and Fleets Sir Herbert Mackay Ellis, K.C.B., K.H.P., Director-General of the Medical Department of the Royal Navy, has this day been placed on the retired list at his own request (dated May 11th, 1908).

The following appointments are notified:—Fleet-Surgeons: R. H. Nicholson, to the *President*, additional, for three months' course at London Hospital; and G. G. Borrett, to the *Royal Arthur*. Staff-Surgeons: W. K. Hopkins, to the *Royal Arthur*, temporary; S. H. Birt, to the *Crescent*; O. Rees, to the *Fox*, on commissioning; F. A. Capps, to the *Mercury*; and R. Waterfield, to the *Challenger*. Surgeons: C. A. G. Phipps, to the *Psyche*; and R. Willan, to the *Donegal*.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors (dated April 29th, 1908): Alexander J. MacDougall and Maurice Swabey.

TERRITORIAL FORCE.

Royal Army Medical Corps.

The undermentioned officers to be Colonels and are appointed Administrative Medical Officers of Divisions:—Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Peter B. Giles, from the 1st Herefordshire Volunteer Rifle Corps (dated April 1st, 1908); Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Andrew Clark (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, 2nd London Volunteer Infantry Brigade), from the 4th Middlesex (Kensington) Volunteer Rifle Corps (dated April 1st, 1908); Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Philip E. Hill (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, South Wales Border Volunteer Infantry Brigade), from the 1st Volunteer Battalion, The South Wales Borderers (dated April 1st, 1908); Lieutenant-Colonel and Honorary Colonel William Coates, C.B., from the Manchester Companies, Royal Army Medical Corps (Volunteers) (dated April 1st, 1908); Lieutenant-Colonel and Honorary Colonel Sir George T. Beatson, K.C.B., from the Glasgow Companies, Royal Army Medical Corps (Volunteers) (dated April 1st, 1908); Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Joseph W. Blandford (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, Tees Volunteer Infantry Brigade), from the 1st Volunteer Battalion, The Durham Light Infantry (dated April 1st, 1908); Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel John R. Thomas (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, Devonshire Volunteer Infantry Brigade), from the 4th Volunteer Battalion, The Devonshire Regiment (dated April 1st, 1908); Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel George S. Elliston (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, Suffolk Volunteer Infantry Brigade), from the 1st Volunteer Battalion, The Suffolk Regiment (dated April 1st, 1908); Lieutenant-Colonel and Honorary Colonel James Turton (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, Sussex and Kent Volunteer Infantry Brigade), from the Sussex and Kent Bearer Company, Royal Army Medical Corps (Volunteers) (dated April 1st, 1908); Surgeon-Lieutenant-Colonel Charles A. MacMunn (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, Staffordshire Volunteer Infantry Brigade), from the 3rd Volunteer Battalion, The South Staffordshire Regiment (dated April 1st, 1908); Lieutenant-Colonel de Burgh Birch, from the Leeds Companies, Royal Army Medical Corps (Volunteers) (dated April 1st, 1908); Lieutenant-Colonel John S. Riddell, M.V.O., from the Aberdeen Companies, Royal Army Medical Corps (Volunteers) (dated April 1st, 1908); Major William P. Whitcombe (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, Worcester and Warwick Volunteer Infantry Brigade), from the Worcester and Warwick Bearer Company, Royal Army Medical Corps (Volunteers) (dated April 1st, 1908); and Surgeon-Lieutenant-Colonel Damer Harrisson (late of the Lancashire Hussars Imperial Yeomanry) from the retired list (dated April 1st, 1908).

1st East Lancashire Field Ambulance: Major John Bently Mann, from the Manchester Companies, Royal Army Medical Corps (Volunteers), to be Lieutenant-Colonel, and is appointed to command the unit (dated April 1st, 1908).

IMPERIAL YEOMANRY.

Scottish Horse: Surgeon-Lieutenant David M. Macdonald to be Surgeon-Captain (dated March 31st, 1908).

VOLUNTEER CORPS.

Rifle: The Queen's Rifle Volunteer Brigade, The Royal Scots (Lothian Regiment): Supernumerary Surgeon-Major Arthur D. Webster (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, 1st Lothian Volunteer Infantry Brigade), to be Surgeon-Lieutenant-Colonel, remaining supernumerary (dated March 26th, 1908). Surgeon-Lieutenant Laurence W. Pole resigns his commission (dated March 31st, 1908). 3rd (Sunderland) Volunteer Battalion, The Durham Light Infantry: Surgeon-Lieutenant William B. Milbanke to be Surgeon-Captain (dated March 10th, 1908). 1st (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and

INLAND WINTER HEALTH STATIONS.

Gudbrandsdal and its immediate district and adjacent valleys offer special opportunities for the sportsman and health seeker, and as the railway extends along the valley from Lillehammer as far as Osta the health stations in this neighbourhood are fairly readily accessible.[5] Chief among the all-the-year-round resorts must be placed *Tofte Sanatorium* (Fig. 4) which your Commissioner, through the kindness of Mr. John Sörensen, was enabled to visit. Here at an altitude of about 1900 feet above sea-level and 1200 feet above the valley on a spur of the mountain side Mr. Sörensen has established a thoroughly homely and in every way delightful winter retreat, where under almost ideal conditions the brain-fagged and bodily-wearied worker may recuperate or the convalescent regain strength. The establishment consists of two villa-like residences so placed as to secure far-extending views and free exposure to sunlight. The houses are of wood, exceedingly warm and snug, and all the rooms are heated with soapstone stoves. The proprietor, who is himself a sufferer from asthma, has established this delightful station primarily for his own health's sake, but possessing wide sympathies and an intimate knowledge of England and other lands he hospitably opens his home to guests from all countries. Mr. Sörensen has taken an active part in educational work and has done much for the development of Norway. He has also established a charming summer hoifjelds sanatorium at Lauvaasen, on the mountain plains above Tofte, at an elevation of 3000 feet above the sea.

The *Fefor Mountain Hotel*, near Vinstra railway station, is open for the Christmas holidays and from February to April.

The *Feforhampens Hotel* and *Hoifjelds Sanatorium*, situated in Nordre Frou, 12 kilometres distant from Vinstra railway station at an altitude of 3000 feet, is open throughout the year.

During the summer many other establishments are open and considerable numbers of visitors take small houses and bring their families for the free and open life of the high mountains. Visitors to this district should on no account miss seeing the admirable collection of old Norwegian houses from Gudbrandsdal with their ancient furniture and equipment, now belonging to the town of Lillehammer.

Tonsaasen Sanatorium (Fig. 5) is situated in Valdres at an altitude of 2020 feet. It was originally established for consumptives but has now been rebuilt and tuberculous cases are excluded. It is open all the year round and affords facilities for every kind of sport. Convalescents, neurasthenics, and delicate and overworked patients are received, but many resort here for holidays and recuperation and the special outdoor pursuits of winter. The rooms are large, picturesque, and artistically adorned, electrically lighted and centrally heated with stoves. There is a resident physician. Inclusive prices vary from kr. 140–240 per month, according to the size and position of room.[6] The railway is within easy drive and Tonsaasen is only about half a day's journey from Christiania.

Within the limits of this article it has only been possible to touch on some of the most likely centres which at the present time might well be expected to attract and to meet the requirements of English visitors. It should, however, be clearly understood that Norway possesses almost limitless possibilities in regard to the supply of first-class winter health and sports stations. At present it is waiting for the demand but by a wisely directed anticipation Norway may go far to create the demand.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8977 births and 4433 deaths were registered during the week ending May 9th. The annual rate of mortality in these towns, which had been equal to 15·2, 15·4, and 15·7 per 1000 in the three preceding weeks, declined to 14·2 in the week under notice, a lower rate than has prevailed in any previous week of this year. During the first six weeks of the current quarter the annual death-rate in these towns has averaged only 15·5 per 1000, and in London the rate did not exceed 15·2 during the same period. The lowest annual death-rates in the 76 towns during the week under notice were 6·6 in King's Norton, 7·9 in Willesden, 8·0 in Walsall, and 8·4 in East Ham; the rates in the other towns ranged upwards to 19·6 in Merthyr Tydfil, 19·8 in Tynemouth, 20·1 in Liverpool, 23·0 in Preston, and 23·1 in Huddersfield. The death-rate in London during the week did not exceed 13·8 per 1000. The 4433 deaths in the 76 towns during the week showed a decline of no less than 463 from the number returned in the previous week, and included 329 which were referred to the principal epidemic diseases, against numbers ranging between 487 and 376 in the six preceding weeks; of these, 115 resulted from measles, 99 from whooping-cough, 42 from diarrhœa, 31 from diphtheria, 24 from scarlet fever, and 18 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases last week were equal to an annual rate of 1·1 per 1000, against 1·2 in each of the three preceding weeks; the rate from the same diseases in London did not exceed 1·0. No death from any of these epidemic diseases was registered last week in Blackburn, Norwich, Wolverhampton, Wigan, York, or in eight other smaller towns; the annual death-rates from these diseases, however, ranged upwards to 3·0 in Wallasey, 3·1 in Rhondda, 3·9 in Salford, and 4·6 in Bootle. The fatal cases of measles in the 76 towns, which had been 101 and 128 in the two preceding weeks, declined again to 115 last week; this disease caused the highest death-rates, 2·0 in Stockton-on-Tees and in Rhondda, 2·3 in Wallasey, and 2·8 in Salford. The deaths from whooping-cough, which had ranged from 204 to 122 in the six preceding weeks, further declined last week to 99; they caused, however, death-rates equal to 1·5 in Bootle, 1·7 in Barrow-in-Furness, and 2·0 in Merthyr Tydfil. The 42 deaths attributed to diarrhœa were fewer by 10 than the number in the previous week, and the 31 fatal cases of diphtheria showed a further decline of seven from recent weekly numbers; diphtheria caused four deaths in Liverpool, three in Manchester and Salford, and two each in West Ham, Portsmouth, Leeds, and Cardiff. Of the 24 deaths from scarlet fever, also showing a decline from recent weekly numbers, 13 occurred in London and its suburban districts and four in Liverpool. The 18 deaths referred to "fever" included five in Liverpool and Bootle and three in Manchester. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had been 2861 and 2928 at the end of the two preceding weeks, had declined again to 2870 on May 9th; 353 new cases were admitted to these hospitals during the week under notice, against numbers increasing steadily from 297 to 368 in the four preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 301 and 281 in the two preceding weeks, further declined to 228 during the week under notice, and were 27 below the corrected average number in the corresponding week of the five years 1903–07. The 28 deaths directly referred to influenza in London showed an increase of nine upon the number returned in the previous week. The causes of 56, or 1·3 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in Leeds, Bristol, West Ham, Bradford, Nottingham, and in 45 other smaller towns; 10 uncertified causes of death were, however, registered in Liverpool, five in Birmingham, five in Preston, five in Gateshead, and three in Tynemouth.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 18·8 and 18·7 per 1000 in the two preceding weeks, declined to 17·8 in the week ending May 9th, but exceeded by 3·6 the mean rate during the same week in the 76 English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 14·2 and 15·0 in Leith and Paisley, to 22·2 in Perth and 22·3 in Dundee. The 629 deaths in these eight towns showed a further decline of 29 from the numbers returned in recent weeks, but included 77 which were referred to the principal epidemic diseases, against 68 in the previous week;

---

[5] Particulars of many of the health stations in this district can be obtained from a well-illustrated manual, "Gudbrandsdalen og Lillehammer Reisehaandlog" (Kristiania: Trykt i Centraltrykkeriet, 1905), an English edition of which should be prepared without delay.

[6] The Scandinavian *krona* (kr.) containing 100 öre (ö) is roughly equivalent to 1*s.* 1½*d.*, or 27 American cents or 1 franc 39 centimes in French money.

of Christ. One cannot, therefore, help attaching primary importance to the living portion of the thankoffering of June 24th. I dislike using the word "success" in this connexion, yet one must feel that the true measure of success of the Church's offering that day will be, under God, in proportion to the number of living members of the Body of Christ who then offer themselves for the work of the Church in far distant lands. And I want, while there is yet time, to call attention to one special direction in which most urgent need exists in the hope that it may then be supplied. I refer to the work of female medical missions.

I will not attempt to dilate on the importance of that particular agency for the spread of the Kingdom of our Blessed Lord. I will only say that each year of added experience and work in India deepens in my heart the conviction of its extreme value and of the impossibility of attaining similar results in any other way. May I, therefore, express my most earnest hope—a hope shared by so many now in the front of the Church's battle—that amongst those who then offer themselves for the King's service there may be not a few thoroughly qualified lady doctors and nurses. It is with deep regret that I learn that so far no offers of this kind have been received. Within the last few months some grievous gaps have occurred in the ranks of my own old mission at Delhi in this particular department, and one longs intensely to see these filled. But why particularise when the need is so widespread and so urgent! Will many join in prayer that it may be at this time largely met?

I am, Sir, yours faithfully,

Killiney, May, 1908. G. A. LAHORE.

THE EPIDEMIOLOGY OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—In the above question I have always been most interested, more especially when there has been a possible relationship between the diphtheria of man and the diphtheria of the lower animals. For many years I had noticed the affection called roup, a laryngeal affection of the fowl, simulating in many ways the affection diphtheria in the child, and I had hoped some time or another to find a connexion between the two diseases.

Some few years ago I was medical officer of health of an urban district in the north of London; I was also in general practice. On one occasion I was called to see a child who suffered with a severe attack of laryngeal and tracheal diphtheria; within a few hours another child, a sister of the first child infected, became ill with true diphtheria. In tracing the cause of illness I found in the back yard of the house some fowls confined in the usual cramped chicken run in which was scattered the contents of ashbin, dust, cinders, and particles of food, mixed with chicken soft food and excreta, the whole wetted with rain-water and smelling most offensively. Two of the fowls had died from what the owner called the "croup," because the noise made by the fowl resembled the sound made by the breathing of a child with croup and similar to the child who was suffering with diphtheria. Two other fowls in the run were standing with ruffled feathers and heads tucked under wings, and appeared very ill. As the two children with diphtheria had been allowed to sit in the run and play with the fowls on several days up to the time they were ill I thought now my opportunity had come to prove the connexion between chicken roup and diphtheria of the human being. I purchased one of the sick fowls and had it conveyed in a basket with all haste to Professor G. S. Woodhead, then chief of the laboratories for research of the Colleges of Physicians and Surgeons of London. I related to him my suspicions. The fowl was examined by him, the mucous membrane of the throat was scraped and further examined; the fowl was killed and examined again after death. Professor Woodhead reported that after every kind of examination he could find no organism resembling in any way the Löffler bacillus of diphtheria in the fowl's mucous membrane. This evidence convinced me that the illness in the fowl somewhat resembling the diphtheria of the human being had no connexion the one with the other.

Since I have been medical officer of health in East Sussex I have also given this matter attention because of the large trade in poultry carried on in Sussex, this trade requiring a number of fowls to be kept in close confinement and fed by hand, &c., as well as the employment of women, men, and children at times in picking the feathers from the dead fowls and the process known in the trade as stubbing. The chief nuisance in connexion with this fattening of fowls is that caused by the offensive smells from the collection of the excreta. In the outbreaks of diphtheria, especially where poultry has been kept, I have tried to find some connexion between the poultry illness and the diphtheria and have failed. I have found those persons closely engaged in the fattening and feeding of poultry, &c., free from the illness diphtheria, while those not engaged in this trade have suffered from diphtheria.

With regard to this question of the possible relationship of diphtheria between fowls and human beings it is interesting to read the classical report to the Local Government Board by Dr. Airy on an epidemic of diphtheria at Buxted and Maresfield in the Uckfield rural sanitary district, July, 1888. The Uckfield rural sanitary district forms part of the sanitary combined districts of East Sussex, to which I was appointed in the year 1897. Early in the report Dr. Airy states: "At many of the small farms in the district, especially where cows are kept, chicken are fatted in large numbers for the London market. At one of them, not the cleanest, a child died of diphtheria early in the outbreak, but the illness could be otherwise accounted for, and there seemed no reason to attribute it to the fowls." Again, "In one or two instances, in answer to my inquiries, mention was made of some ailment or other among fowls, but in no case was there anything suggestive of dependence of the human disease upon any such ailment nor upon any disease of the lower animals."

I am, Sir, yours faithfully,

HUGH STOTT,

Medical Officer of Health of the Combined Sanitary Districts of East Sussex.

Lewes, Sussex, May 5th, 1908.

THE LONDON DIOCESAN CHURCH LADS' BRIGADE.

To the Editor of THE LANCET.

SIR,—Having the honour to be principal medical officer of the London Diocesan Church Lads' Brigade I wish to point out to the members of my profession the voluntary and excellent work being done by the officers of the brigade in gathering together the lads of the diocese and promoting amongst them habits of reverence, obedience, self-control, and all that tends towards Christian manliness. It is not for me to dwell upon the splendid results already attained; but as principal medical officer I take a keen interest in that branch of the work which comes immediately under my supervision—namely, ambulance and first aid.

There are at present 43 companies in which instruction in ambulance and first aid is being given, and it is only the lack of qualified medical men to act as lecturers that prevents the work being enormously extended. Companies in every part of London are eagerly waiting to welcome instructors, and I shall be glad if any medical men who can spare the time to give lectures weekly or fortnightly would communicate with the honorary secretary for ambulance, Captain Fred. W. Jones, 28, Sach-road, Upper Clapton, N.E.

Gentlemen offering their services have the option of being gazetted officers in the Brigade or not, as they wish. On receipt of any such names I shall be glad to interview or write very fully, giving all details, for the importance of this work cannot be over-estimated. The Brigade consists of 170 companies who meet together every Sunday for religious instruction and are also regularly trained in all branches of military drill, in addition to which seaside camps are held in August at Bexhill and Eastbourne.

I am, Sir, yours faithfully,

J. FAYRER, M.D. St. And.,

Lieutenant-Colonel, R.A.M.C., Principal Medical Officer L.D.C.L. Brigade.

Duke of York's Royal Military School,
Chelsea, S.W., May 6th, 1908.

PRESENTATION TO A MEDICAL PRACTITIONER.—At the distribution of prizes and certificates to the members of the Bristol branch of the Midland Railway Corps of the St. John Ambulance Association, which took place at Bristol on May 6th, Mr. James Smith Mather, M.B., C.M. Aberd., was presented with a clock as a mark of esteem and in recognition of his valuable services to the corps.

Sutherland Highlanders): Surgeon-Captain Alexander Leitch to be Surgeon-Major (dated March 23rd, 1908).

Royal Garrison Artillery (Volunteers): 1st Kent: Surgeon-Lieutenant Sanderson Mellor resigns his commission (dated March 31st, 1908).

Rifle: 3rd Volunteer Battalion, The Prince of Wales's Own (West Yorkshire Regiment): Surgeon-Lieutenant George E St. C. Stockwell resigns his commission (dated March 31st, 1908). George Ephraim St. Clair Stockwell (late Surgeon-Lieutenant) to be Lieutenant (dated March 31st, 1908). 2nd Volunteer Battalion, The Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): The undermentioned officer resigns his commission: Surgeon-Lieutenant Herbert Shipton (dated March 31st, 1908). 1st Volunteer Battalion, Princess Charlotte of Wales's (Royal Berkshire Regiment): Surgeon-Captain William M. Parham, resigns his commission (dated March 28th, 1908). 2nd Volunteer Battalion, The Queen's Own (Royal West Kent Regiment): The undermentioned officer resigns his commission, with permission to retain his rank and to wear the prescribed uniform: Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Henry W. Roberts (dated March 31st, 1908). 4th (Donside Highland) Volunteer Battalion, The Gordon Highlanders: Surgeon-Captain David Maver resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 25th, 1908).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Northern Command: Leeds Companies: Captain Herbert J. Robson resigns his commission (dated March 31st, 1908). North-East Lancashire Bearer Company: William Fraser Munro to be Lieutenant (dated March 23rd, 1908).

DEATHS IN THE SERVICES.

Brigade-Surgeon William Pierce Kelly, retired pay, I.M.S., on May 2nd, at Dublin, aged 73 years. He entered the service as assistant surgeon in 1857, became surgeon in 1869, surgeon-major in 1873, and retired with the rank of brigade-surgeon in 1884. He took part in the Indian Mutiny campaign of 1858 and served with the North Canara Field Force (medal).

Brigade-Surgeon Edward Harford Lloyd, retired pay, Army Medical Service, on May 3rd, aged 72 years, at the Royal Naval Hospital, Chatham. He entered the service as assistant surgeon in 1859, became surgeon in 1873, surgeon-major in 1875, and retired with the honorary rank of brigade-surgeon in 1885. He served in the Soudan during the Nile expedition, 1884–85, and was in charge of the field hospital at Kaibar (medal with clasp and Khedive's bronze star).

THE TERRITORIAL FORCE AND THE RED CROSS SOCIETY.

The Army Council has directed the attention of the County Territorial Force Associations to the proposals made by the committee of the British Red Cross Society and approved by the Army Council for assisting in the relief of suffering and the care and disposal of the sick and wounded when the Territorial Force is mobilised for war. It is now desired to bring all county associations into communication with the Red Cross Society's county branches; and though the Army Council is not prepared to say at present what assistance the society may in the future be able to render to the first and second lines of medical assistance in the field, it is suggested that consideration may be given to the work that the society can undertake in respect to the general hospitals of the third line, and on the lines of communication, all in rear of the field army. The work in which the society can participate is summarised as provision of quarters and equipment for 23 general hospitals and of a certain proportion of the staff to supplement the permanent nucleus maintained and trained in peace time; arranging for the transport of sick and wounded; the establishment of refreshment stations on the lines of communication; and the formation of convalescent homes for officers and men.

INDIAN MEDICAL SERVICE EXAMINATIONS.

An examination for not less than 20 commissions in His Majesty's Indian Medical Service will be held in London on Monday, July 27th, and the five following days. Particulars regarding pay, promotion, &c., in the Service and the necessary forms of application can be obtained from the Military Secretary, India Office, London, S.W. Applications must reach the India Office on or before July 14th.

CHOLERA IN INDIA.

A *Times* telegram, dated Peshawar, May 12th, states that: "Owing to a few additional cases of cholera the 1st Northumberland Fusiliers and the Munster Fusiliers will not accompany General Willcocks's force against the Mohmands."

Count Benckendorf, the Russian Ambassador, through General Yermaloff, Military Attaché, by special order of the Empress Marie Feodorovna, President of the Imperial Russian Red Cross Society, has presented Major E. Hautonville Richardson with the war medal of the society, together with a letter conveying the heartfelt thanks of the society, for the services of his ambulance dogs in Manchuria during the Russo-Japanese War.

A Colonial Office telegram from Singapore states that Mr. C. T. Raikes, M.B. Oxon., M.R.C.S. Eng., L.R.C.P. Lond., Government medical officer, has died from plague contracted while performing a post-mortem examination. Mr. Wray, an assistant of Dr. Raikes, is also reported to have died.

Correspondence.

"Audi alteram partem."

RESEARCH DEFENCE SOCIETY.

To the Editor of THE LANCET.

SIR,—The committee of the Research Defence Society will be greatly obliged to you if you will make known the following facts. The society has at present about 1100 members, of whom about 100 are ladies. The following gentlemen have recently consented to be Vice-Presidents of the society: The Marquis of Salisbury, Lord Ludlow, Mr. Briton Rivière, Earl Egerton, Sir William Turner, Lord Fortescue, Sir Thomas Fraser, Sir John Banks, the Bishop of Chester, and Count Plunkett. By the death of Lord Poltimore, who also was a vice-president, the society has lost a good friend.

The *minimum* subscription for membership is 5*s.* yearly; but medical students are eligible for membership for a subscription of 2*s.* 6*d.* and it is to be hoped that a very large number of students will join the society. Branch societies are already being formed in many parts of the country. A considerable quantity of leaflets and pamphlets has been sent out in reply to requests for them; and the printing of other leaflets and pamphlets is going on rapidly. These publications include an essay by Colonel David Bruce on the Extinction of Malta Fever, an essay by Professor Cushny on the Experimental Study of the Action of Drugs, reprints of Lord Justice Fletcher Moulton's evidence before the Royal Commission, and of Professor Osler's evidence on Yellow Fever and Malaria; and leaflets on diphtheria antitoxin, the administration of the Act, the character and extent of the researches made in this country at the present time, the facts about curare, &c.

Arrangements are being made for an inaugural meeting of the society at an early date in London. Arrangements are also being made for debates in London or elsewhere, but, of course, the committee do not think it necessary to accept every "challenge" to a debate. The committee feel very strongly the urgent need of branch societies, and of corresponding members in those places which are not large enough for a branch society. They are well aware that the work of the Research Defence Society must be done all over the country and that no further advance can be made except by united and organised effort. They will be very happy to receive promises of help in this matter. The Research Defence Society has had a magnificent welcome and is bound to justify the confidence which the public has given to it.

I am, Sir, yours faithfully,
STEPHEN PAGET, Hon. Sec.

70, Harley-street, London, W., May 13th, 1908

THE PAN-ANGLICAN THANKOFFERING: FEMALE MEDICAL MISSIONS.

To the Editor of THE LANCET.

SIR,—If it is true that a country's wealth consists not in her Consols and hard cash but in her sons and daughters—and one is thankful to know that on every side this is being increasingly recognised—still more is this true of the Church and on closing most probably the very place or valve that should be opened. The ideal would be a system out of reach of the passengers ignorant of the complexity of ventilation problems and one which would supply so slow and well diffused a current of air as to be imperceptible. For this purpose the air should nowhere travel at a greater velocity than three feet per second. Yet I was told that in the smoke-room of the *Adriatic* the air could be made to travel at the rate of 70 feet per second, or close upon 50 miles an hour. No one could sit quietly and smoke in such a hurricane. The danger, therefore, on such ships would be too much ventilation, causing protests and leading to the complete closure of the ventilators, with the result that there might be no ventilation at all. The evils of these two extremes can only be avoided by the intelligent forethought and watchfulness of the attendants.

In dealing with the ventilation of the great transatlantic liners it has been my object to derive from such experience some lessons that might have a useful application on shore as well as at sea. Indeed, I have compared these big ships to floating cities where rich and poor, idle and industrious, live together. The force of circumstances has taught this great lesson that on board ship the best results are attained at the least cost by applying one and the same system of ventilation, heating, and drainage to the entire community. Are we sure that this rule is not equally applicable on land? It will be said that at sea there are the water and the waves to fight against entailing the restriction of space by compelling all to live together in the one ship. But on shore are there not also restrictions of space due not to the surrounding waters but, at least in large industrial centres, to the prohibitive cost of building land? Then if on shore there is not the same danger of water in the shape of huge waves dashing in upon us there is very often a constant invasion of the dwelling by volumes of dust, dirt, smoke, and vitiated atmosphere. These evils at least are absolutely unknown at sea. May not collective action be as necessary to cope with the evils of town life as with those of life at sea? Already, in regard at least to drainage, it is recognised that there should be a general system applicable equally to the dwellings of the poor as of the rich. Certainly I can testify from personal experience that common lodging-houses in London, where beds are obtained for 4*d*. a night, are as well drained as, and sometimes better drained than, the mansions of Mayfair. The equality in the sanitary principles which apply on the *Mauretania*, as well to the lavatories of steerage passengers as to those used by the millionaire who pays £200 for a suite in crossing the Atlantic, exists here on shore and in London. Indeed, some years ago I visited a mansion in an aristocratic neighbourhood belonging to a peer and found the drainage in a most dangerous and defective condition. In the better inspected common lodging-houses and slums of London nothing similar would be tolerated. Thus, then, and as far as constant sanitary inspection can bring this about, there is no difference permitted in regard to the sanitary efficiency of the systems of drainage allowed in dwellings, whether these be inhabited by the rich or the poor. It may be said that, so far as drainage is concerned, people who live on shore compare favourably with the dwellers on board these new floating towns such as the great transatlantic liners which I have recently described.

In regard to warming and ventilating the position is very different. On shore there is not, as a rule, collective enterprise in these respects. Each individual having to do the best he can for himself, the result is very unequal and unsatisfactory. But there can be no doubt that by association the burden of each individual might be considerably lightened and the general result very much improved. Nor has this fact been demonstrated only at sea. We have our *Mauretanias* and our *Lusitanias* on shore as well as on sea. The newly constructed Midland Hotel at Manchester may very appropriately be compared to the great liners. The population on board each of these ships may amount to 3250 persons, including a crew of 800 skilled and unskilled workers. The crew—that is, the staff—of the Midland Hotel is naturally not so large, for on board these ships there are 390 persons in the engineering and 70 in the sailing departments which are not needed at a hotel. Nevertheless the staff of the Midland Hotel numbers more than 400 and this may be compared with the 350 stewards and the 50 cooks of the *Lusitania* and her sister ship. The point is the same in either case. In the hotel as on board the ship there are some hundreds of workers earning a modest wage and yet they are supplied by machinery with the same carefully prepared and scientifically distributed supply of air to breathe. Thus mechanical ventilation is not inaccessible to the working class when the expense involved is shared by other and more fortunate members of the community. Indeed, the expense is not great if it is only incurred on a sufficiently large scale. In towns like Manchester there is a double reason why this should be done. Not only is ventilation—that is, a sufficient supply of air—required, but pure and clean air is needed. This does not exist in Manchester and can only be obtained by employing artificial means. Here, again, no one individual could afford to do this only just for himself and his household. But what the individual or the family cannot attempt a huge institution like the Midland Hotel may carry out with ease. Here under the same roof several hundred families can be accommodated and the cost of scientific ventilation when divided among so many represents but a small amount for each individual. Indeed, it is not dearer to live at the Midland Hotel of Manchester than in other equally luxurious establishments where no such elaborate mechanical means of ventilation have been applied; also there is a further economy in allowing only clean air to enter a building, for the furniture, hangings, clothes, walls, paintings, in fact, all that is within, remain clean for a much longer time. There are therefore less washing and other forms of cleansing needed and consequently there are less wear and tear. All who have been to Manchester know how quickly their linen and persons are soiled by the sooty atmosphere created by the many surrounding manufactories.

This grievance does not, however, exist within the Midland Hotel. There the visitor may hope to keep clean, for everything around him is clean. But such a result was not obtained without considerable care and trouble. The building is as elaborately ventilated as are the transatlantic liners and, further, the air is specially treated before it is admitted within the building. At a height of 70 feet from the basement, situated within an inner court, is the air inlet. Here the heavier dust from the streets cannot reach the inlet. It consists of two shafts each 12 feet square. These run down the side of the main wall, and the air, attracted by powerful fans, is treated in the basement of the building. First it is delivered against a series of screens placed zig-zag and covered with American cheese-cloth. By this means 360 square feet of filtering surface are opposed to the inrush of air. Once or twice a day in very clear weather, five or six times a day in very foggy weather, a vacuum cleaner has to be passed over all this filtering cloth, otherwise it would be soon choked up by the amount of dirt which it extracts from the air. On one occasion, in the month of October, the dirt thus retained was analysed and found to be composed of 19·5 per cent. of insoluble organic matter, consisting chiefly of soot with small quantities of hair and similar materials. The soluble matter present, mainly ammonium salts, amounted to 13·3 per cent.; the insoluble inorganic matter, chiefly sand, was 30·9 per cent., and 36·3 per cent. consisted of soluble mineral matter, such as salts of iron, sodium, potassium, ammonium, with traces of copper, aluminium, manganese, calcium, and magnesium. Such is the nature of the suspended matter that abounds in the atmosphere which the ordinary inhabitant of Manchester breathes. This is a very emphatic demonstration of the necessity of artificial mechanical ventilation in such dirty manufacturing centres as Manchester.

The cheese-cloth filter, however, does not suffice. After passing this first obstacle the air is drawn through a coke filter six inches thick, which has a superficial area of 224 feet. Here it leaves so much more dirt that the coke has constantly to be renewed, though no less than 400 gallons of water per hour are expended in the endeavour to keep it clean. Thus the air goes through a dry filter of American cheese-cloth first and then a wet coke filter six inches thick before it is considered sufficiently washed and cleansed. Between the two filters there are some steam coils to prevent the water freezing in winter, while in summer ice can be placed here so as to cool the air. In this underground department the walls are of white glazed bricks. These white bricks which are on the outside of the filter become, in spite of their glazed surface, absolutely black in the course of three weeks and have constantly to be washed. On the other side of the two filters all is beautifully clean. In the morning of my visit I found the temperature here was at 45° F. and in the winter garden above 58° F.

After the air filters come heating batteries in eight sections. They consisted of coils made of inch tubes and

THE VENTILATION PROBLEM AT SEA AND ON SHORE.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE "ADRIATIC" AND THE MIDLAND HOTEL, MANCHESTER.

THE White Star liner *Adriatic* is the third largest ship afloat. The *Lusitania* and the *Mauretania* of the Cunard line have their tonnage estimated at 32,500 and the *Adriatic* is 25,000. These three huge ships can each carry more than 3000 persons and therefore present all the sanitary and social problems to which I have alluded at length when describing the *Lusitania*.[1] We have the problem of ventilating luxurious saloons and overcrowded steerage. The poor emigrant and the millionaire are on board the same ship and depend on the same mechanical contrivances for the air which they breathe. The *Adriatic*, however, differs from the two great Cunarders inasmuch as it does not apply the plenum system of ventilation. On the contrary, it exhausts the air. The idea is to use power to draw out the foul air and to trust the fresh air to find its way in unaided. Nevertheless, this principle is not observed throughout. Some of the fans, for the most part electric fans, propel the air into the ship; but, as a rule, motive power is used for suction purposes. In these circumstances the action of the port-holes and ordinary inlets is a matter of much greater importance. Thus, on the saloon deck, where numerous small passages intersect the cabins, these have each a porthole provided with Uttley's ventilator. This is a system by which though the port is shut and waves may dash up against the pane of glass, nevertheless there is an aperture above by which the air can enter but not the water. Therefore, if the air is drawn out by machinery it will enter through the port-holes automatically. The cabins giving on to the promenade deck have windows for air inlets on one side and on the other side in the passages the air trunks overhead act as suckers to draw the air away. As for heating, that is not connected with the ventilating system. In saloons or passages, in fact, wherever the cold is likely to be felt, there are steam coils and some of the more luxurious suites of rooms have powerful electric heaters that can be turned on or off just as the passengers may desire.

In the great dining saloon there are openings all round in the wainscoting and also in the central ornamental glass dome. These openings communicate with trunks connected with rotating fans which produce an exhaust and draw air away by these channels. Some of the air comes in by the doors which are constantly opened and shut. Then there is a special draught-screen placed in front of the port-holes so that the air coming from them is sent upwards towards the ceiling. This being made of glass the light can pass straight through but the air is deflected. Close by in the pantry and kitchen there are several special suction trunks and a high shoot or shaft going up to the deck from the kitchen, and there is also a special trunkage just over the stove to draw the heat away. The power of the fans employed is such that, according to the experiments made, it would be possible to change the air of the saloon gallery in half a minute. The first-class smoke-room has special air inlets measuring 2·25 square feet and three sets of doors. The outlet surface in all measures 2·87 feet. In these latter so strong a suction can be produced that the air could be made to travel at the rate of 70 feet per second and the whole of the air removed in but little more than a minute. But, of course, this would not be endurable; however, the smoke, I was assured, is removed so rapidly that there is no unpleasant accumulation of tobacco fumes and yet there is no inconvenience due to draughts. The air of the saloon reading-room can be changed in one minute and that of the lounge in three minutes.

In the lower portions of the ship, on the main deck, where there is no promenade deck and the natural openings, the port-holes, are near to the water line, these chance air inlets are no longer sufficient. Consequently, it is necessary to pump air down as well as to draw air out. For this purpose a double set of air trunks or channels are needed. In the second class it appears as if there was more ventilation, certainly there is more artificial ventilation than in the first class. But in one place I found an inlet so near to an outlet that the fresh air must have passed straight from one to the other without doing much to improve the surrounding atmosphere. For the steerage on each side of the deck there are two very powerful fans 4 feet in diameter. In case of accident a by-pass would place the two sets of air-channels in communication, so that one fan could supply air to both sides of the ship. All the cabins have openings above the doors or near to the ceiling, and thus they participate in the great and constant movement of air that occurs in the passages outside the cabins. It is only because such powerful mechanical means of ventilation have been employed that it was possible to establish on board an innovation which distinguishes the *Adriatic* from all other ships afloat. The German ships had already instituted mechanical gymnasiums and these are also to be found on the *Adriatic*. Machinery provides a very good imitation of horse riding for ladies and gentlemen. Or they may have rowing exercise or experience various forms of massage by machinery. But close to this gymnasium there is a luxuriously appointed Turkish bath and this is not to be found on any other ship. There is a small hot room, a fairly large temperate room, and a large cooling room. Then there are two shampooing rooms, douche, and so large a plunge bath that it is possible to swim a few yards. Finally, there are three rooms for light baths, electric baths, and couches for massage. Naturally, all the air has to be supplied artificially to these departments, particularly as they are low down on the main deck and have four decks above them.

Throughout the ship the lavatories draw air through louvred doors from the passages towards the strong suction trunks within. Thus no air goes from the lavatories into the ship, but, on the contrary, the lavatories are themselves outlets. For the closets Doulton's Arogon basins are employed, and these have an after-flush in case the movement of the ship causes the water seal to be broken. Then a spread-fan distributes the water over the urinals and there are valves to increase or to lessen the flow of water according to the circumstances. It has not been found practical to employ automatic flush tanks on board ship where sea-water is used for these sanitary purposes. Cinders and seaweeds are liable to get into this water and they block up the very small pipes of the automatic flush-tanks.

It will be seen that the *Adriatic* is ventilated on the opposite system to that of the *Mauretania* and the *Lusitania*. The argument used is that though the plenum system employed on these two ships is theoretically the best the exhaust or vacuum system is practically the most effective in the rough-and-tumble usage of a sea voyage. Again, objection is raised to driving heated air along very lengthy air-trunks. If such air is to reach its destination at the required temperature it must be hotter than needed at the commencement of its voyage. Consequently, near and about the point of departure it overheats the air trunks, and this causes inconvenience in the neighbourhood of these superheated portions of the air channels. The thermo-tanks used in connexion with the plenum system warm the air at the point of departure. On the *Adriatic* the air is not heated at all; but radiating heat is supplied in steam coils in all parts of the ship where it is wanted. Which of these two systems is the best I cannot say and to pronounce an opinion must wait till I have had an opportunity of travelling on such ships. At Southampton I went over the *Adriatic* while she was in port and just before her departure when the fans were working and the air was circulating in the air trunks. All I can say is that there exists ample power to change frequently the atmosphere within the ship, but to do this in such a manner as not to cause draughts and inconvenience is another matter. The efficacy of the service must in a large measure depend on attentiveness and on the intelligence of the engineers and stewards in charge. There are certainly inlets which are not sufficiently protected by baffles to break up and so to distribute the air as to prevent draughts. It will be necessary to repeat many times that it does not suffice to supply as much air as is wanted. Above all, this air must be distributed in such a manner as not to cause cold draughts. To neglect this precaution is the sure way of stopping all ventilation, as those who suffer will find some means of closing the ventilator. Therefore, it does not suffice to go over a ship in port and to note a plentiful supply of outlet and inlet ventilating grids, &c. Practical experience is needed and constant observation during a voyage to know how far the system acts and whether the passengers will allow it to act or will insist on interfering

---

[1] THE LANCET, Jan. 4th, 1908, p. 54.

Œdema of the chiasma was liable to appear in acute inflammation of the frontal or sphenoidal sinus. Pressure on the optic nerve might follow an inflammation of the ethmoidal labyrinth. Chronic inflammatory conditions in the posterior accessory nasal sinus might cause changes in the ocular muscles. Injuries during operations on these sinuses might cause post-operative blindness, sometimes on the other side from that on which the operation was performed, if the inner bundle of the chiasma had been injured. Dr. Onodi expressed his hope that coöperation of rhinologists and ophthalmic surgeons would prevent post-operative blindness and that produced by neglected conditions of the nasal sinuses, but he reminded the surgeons that in spite of nasal symptoms blindness might occur from other causes (toxic, neuritic). A large collection of splendid anatomical specimens helped to illustrate the paper, showing that the sulcus opticus was often formed by a wall of sphenoidal or ethmoidal cells.

Dr. GLUCK (Berlin) read a paper on the

Surgical Treatment of Tubercle and Cancer of the Larynx.

He advocated total extirpation of the larynx in complicated cases and partial extirpation in non-complicated cases. The mortality of the operation has been reduced to *nil* in the simple cases, whilst in cases where the pharynx or the glands had to be removed at the same time the death-rate was from 9 to 13 per cent. If the growth extended beyond the region of the larynx itself or if it invaded both halves total extirpation was necessary. He showed five patients without their larynges who were in good health and for several years had been able to work. In cases of metastasis or mediastinal tumours or aneurysms, with compression of the upper air passages, where radical cure was impossible Dr. Gluck established, in order to relieve the dyspnœa, a pulmonary fistula by making a communication between the pectoral wall and one of the larger bronchi. This method had been already hinted at by Professor von Schrötter in his essay on mediastinal growths.

Intranasal Operations.

Professor DENKER (Erlangen) explained his system of performing intranasal operations from the mouth. The method briefly was as follows. He divided the mucosa of the mouth on the upper alveolus, where it begins to descend to the lip on both sides, and by means of an elevator or raspatorium he pushed up the soft parts so far that the whole maxilla and the lower margin of the orbit were accessible. In this way tumours of the nasal fossæ of the maxilla could be readily removed, the turbinals could be easily detached, the ethmoidal labyrinth was accessible, and the choanæ as well as any growths of the pharynx could be reached. The method had been chiefly advised for the removal of neoplasms, and when this had been done the oral wound was primarily sutured after packing the cavity of the bones, and boric acid lotion was used for washing the mouth. Professor Denker had operated on six patients in this way. He claimed that his method gave ready access to the tumour, caused little hæmorrhage, and produced an ideal cosmetic result as compared with the extensive resections of Langenbeck, Kosher, and Nélaton; it required no preliminary tracheotomy or ligature of the carotid vessels and the after-treatment was very simple.

Professor DENKER also read a paper on the treatment of Malignant Disease of the Nose. He said that he was a firm believer in surgical operations for this condition, since all other forms of treatment, such as radium, x rays, and chemical and fermenting or dissolving agents had proved unreliable.

On April 23rd Sir FELIX SEMON read a paper in English on the

General Treatment of Local Diseases of the Upper Air Passages.

He emphasised the necessity of individualisation and explained the generally accepted methods of treatment of lesions of the upper air passages whether depending on syphilis, tuberculosis, malignant disease, catarrhal affections, and general systemic diseases, such as gout and anæmia. He especially warned the profession against publishing reports of alleged cures of malignant disease by remedies which only served as the basis of paragraphs appearing in ordinary newspapers. Trypsin was one of these so-called remedies; it had had enough time to prove its efficiency but failed to do so. In conclusion, he said that nobody could become a good specialist who was not also a good general physician.

Dr. HERYNG (Warsaw) read a paper on

Inhalation as a Therapeutic Factor.

He said that hitherto most forms of inhalation apparatus were open to the objection that the spray which they supplied was too cold. The temperature of the trachea was usually above 98° F., whilst the temperature of the common warm spray did not exceed 88° F. Therefore condensation of the spray could not take place in the trachea or the alveoli unless the spray was much more heated when it entered them. The possibility that liquids might enter the lung in droplets had been proved by Bulling and von Schrötter by means of artificial breathing. Dr. Heryng had constructed three types of spray apparatus, two of which supplied "cold sprays" at temperatures up to 88° F., and "warm sprays" up to temperatures between 98° and 140° F.; the third apparatus was called a thermo-accumulator and was adapted for the vaporisation of heavy aromatic, balsamic, or antiseptic substances at a temperature of about 130° F. In order to make these vapours capable of being inhaled they must be charged with a sufficient quantity of air and steam. The heavy, hot vapours penetrated quickly into all parts of the lung and permeated the walls of the vessels by a quick absorption. They could soon be found in the circulating blood and in the urine, thus proving their applicability in the treatment of general diseases. Dr. Heryng employed his apparatus for the treatment of affections of the nose, throat, larynx, and bronchi, for disinfection in mixed tuberculosis of the lung (secondary infection), and for charging the system with iodine in asthma and arteriosclerosis.

Dr. HERYNG also read a paper on

The Treatment of Tuberculous Disease of the Larynx.

He said that he had made it the business of his life to find a proper treatment for this disease. He advocated early surgical interference with the local growths and the touching of ulcers with a saturated solution of permanganate of potassium or a solution of malachite green of 2 per cent. strength. No efforts should be spared to remove all the disease from the larynx as early as possible, provided that the patient was capable of enduring the shock. A number of patients had made permanent recoveries under this method of treatment. Of course, general treatment afterwards was of the utmost importance. Expectant treatment as a rule did not stop the progress of the disease.

(To be continued.)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Soot and its Derivatives.

MANCHESTER is sending an extensive and varied contribution to the Franco-British Exhibition. Engineering, industrial chemistry, textile work, sanitary and building engineering, photography and printing, commercial method, dyeing in cotton and wool, and many other exhibits illustrative of the extent to which physical science has become the handmaid of commerce will be displayed on the stalls. There will also be some exquisite examples of binding and illuminating, and in close proximity to these indications of refinement "some deadly demonstrations of the wickedness of Manchester's atmosphere," in the form of products obtained by Manchester chemists from "native soot," including among other things caustic soda, phenolic compounds, calcium sulphate, hydrochlorides, oils, ammonium sulphate, pitch, and various hydrocarbons. This imperfect list will suffice to show some of the difficulties which manufacturers and dealers in delicate fabrics have to contend with in order that they may show their customers the goods which they require unsoiled and unblemished. It is no doubt a triumph to achieve success in spite of difficulties, one of which is "the vilest of climates," as that of Manchester is often called, although the natural climate, while rather damp, does not deserve the epithet vile. The landscape would be fairly pleasing if only man had not poisoned the air and made it filthy with the noxious products of imperfectly consumed coal. To remedy this state of things, which renders a great part of Lancashire and Cheshire black and dirty, where the flowers, still able to show how beautiful they ought to be, blacken the hand that gathers them and the country side is robbed of most of its presenting in all 10,000 feet of heating surface. Low-pressure steam circulates within the tubes. To draw the air through the filters and heating batteries and then to propel it forward to all parts of the hotel there are two rotating fans each 120 inches in diameter, driven by two 20 b.h.p. electric motors. The temperature of the air is generally raised to 62° F. In this manner 6,000,000 cubic feet of air are filtered, washed, warmed, and propelled slowly forward in the course of an hour. The total weight of the air treated and moved onwards in an hour is set down at 203 tons. Having thus obtained a sufficient quantity of air and greatly improved its quality by filtering and washing we now come to the greatest difficulty, that of distributing it throughout the building. For this purpose the *plenum* system has been adopted, so far at least as the corridors, the 300 bedrooms, and the 200 or so small apartments are concerned. The air being pumped into the passages there is a greater air pressure than outside. Over every door there is an inlet, often an invisible inlet, so that the air which is under pressure in the passage finds relief by penetrating the rooms that give on to the passage. Once in the room it makes its way to the chimney which constitutes a natural outlet. There are windows but these should not be opened as they would let in the unfiltered and dirt-laden atmosphere of Manchester. The windows are only intended to let in light. The fireplaces are ornamental air outlets and as this air is already warmed there is rarely need to light a fire. The pressure of air in such large corridors is, of course, only slight; consequently it enters and traverses the bed and other rooms so gently as to be imperceptible. But the opening of a window would play havoc with the system, and it will take some time before the public learn that there is nothing more fatal and destructive of scientific ventilation than the promiscuous opening of windows and even of doors.

In all the public rooms, the kitchens, the Turkish bath, and lavatories, there are extraction or exhaust shafts as well as the inlets, so the air is drawn out as well as pumped in. The main extraction shafts abut on the roof and discharge from the north-west tower at 106 feet above the street. It must not be thought that air can be pumped in and drawn out of a room without causing draughts and complaints. For instance, in the octagon court there is a gallery with a glass dome very similar to those of the great dining saloons on the *Mauretania* and *Lusitania*. As a consequence the air became cool when it reached the glass dome and then fell on the heads of the people below. Therefore, hot steam tubes had to be placed all round the dome to warm the air again as it descended. The inlets are generally in the walls about 8 feet above the ground where there are air exhaust on one side and air inlet on the other; anyone sitting between the two is liable to feel a draught. Therefore a louvre arrangement had to be placed inside the grate of the inlets to be worked from the outside so that the air might be deflected upwards more or less and according to the circumstances. Then as there are four and a quarter miles of air trunks subsidiary heating batteries have had to be introduced in these shafts to compensate the cooling of the air while travelling such great distances. Again, in some places the extract aperture was too near the inlet, so the air made a short circuit and left the greater part of the room unventilated. Several alterations were necessary. An immense improvement has been effected but perfection has not been reached and there is constant need of personal and technical supervision. The power of wealth, the love of luxury, and the competition between those who cater for the comfort of those who can afford to pay a high price have helped to bring about these great improvements. The servants, the attendants, and the crews of the ships have also shared in these benefits. But need the advantage stop there? If it pays to ventilate scientifically luxurious ships and hotels would it not also pay to ventilate other places where good air is perhaps even more necessary? Many trades and industries and sweating dens are fatally unwholesome for want of proper ventilation. Could not the experience acquired in providing washed, filtered, warmed, and sufficient air to the wealthy be utilised in devising methods applicable to tenement dwellings and workshops where the poor live and toil?

A MEETING of the British Balneological and Climatological Society will be held at Harrogate to-day, Saturday, May 16th. The society will be accorded a civic reception and will visit several places of interest in the neighbourhood.

THE FIRST INTERNATIONAL CONGRESS ON LARYNGOLOGY AND RHINOLOGY.

(FROM OUR VIENNA CORRESPONDENT.)

THE First International Congress on Laryngology and Rhinology was held in Vienna from April 21st to 25th, and its success may be judged from the fact that a resolution was passed at one of the later sittings recommending that this eminently useful congress should have a permanent organisation with general meetings every four or five years. The number of ordinary members was 467, including 33 from England and Ireland, 28 from the United States of America, three from South America, and two from Japan. Representatives of nearly all the European countries were present and the number of papers read before the Congress was 86. Many papers, however, especially those by Austrian authors, which were left for the last day, were only mentioned at the meeting but will appear in the Transactions *in extenso*. As reported in a previous issue of THE LANCET, an element of sadness was introduced by the death of Professor von Schrötter, the honorary president, who died with tragic suddenness only 12 hours after he had in a brilliant speech commemorated the jubilee of Türck and Czermak. It was a great shock to the members of the Congress when Professor CHIARI, at the commencement of the proceedings on April 22nd announced the death of the famous physician. A committee was at once appointed, Sir Felix Semon being the English representative thereon, to render due honours to the deceased and to attend the funeral.

It must be remembered that in addition to the reading of papers the congress was organised with the further object of doing honour to the memory of Professor Türck and Professor Czermak, both of Vienna, who 50 years ago began to make use of the laryngeal mirror for clinical purposes. The discovery of an instrument of this kind by Manuel Garcia, the famous teacher of singing, was not at that time recognised, and its value was not known until the two Vienna physicians took the matter in hand. Since then, thanks to them and to Professor von Schrötter, laryngology and later rhinology have grown until they have become extensive departments of practical medicine. As a souvenir of the occasion each member of the congress was presented with a medal bearing the portraits of the two laryngologists whose jubilee was thus celebrated, and in the exhibition, to be mentioned later, several objects referring to them were shown.

The congress was formally opened by His Excellency the Governor of Lower Austria who welcomed the members in the name of the Protector, the heir presumptive to the Austrian throne, and assured them that the Government took the greatest interest in the proceedings. The President, Professor Chiari, in an eloquent speech delivered in German, French, and English, then dwelt on the attention paid by the learned societies to the congress and on his suggestion telegrams of respectful greeting were sent to the Emperor and to the Protector. The representatives of the different countries and governments were then called upon to deliver their speeches, which were for the most part very short. Professor VON SCHRÖTTER in the next place delivered a brilliant oration on Professor Türck and Professor Czermak, some relatives of both of whom (sons and grandchildren) were present.

On April 22nd, when Professor von Schrötter's sudden death became known, the Congress adjourned for an hour in token of mourning. Its proceedings were resumed with the reading of a conjoint report by Professor FRÄNKEL (Berlin) and Professor LERMOYEZ (Paris) on

Laryngology and Rhinology and General Medicine: Teaching of, and Examination on, these Subjects in Different Countries.

The professors described the great progress which had been made in medicine by the aid of the laryngoscope. Professor Fränkel emphasised the necessity of diminishing specialism, and at the same time expressed the opinion that the otologist should not suppress the laryngologist. Professor Lermoyez recommended that the medical curriculum of the universities should include an examination in laryngology.

Dr. ONODI (Budapest) read a paper on

The Correlation of Nasal Diseases with Ocular Diseases.

He said that the close anatomical relations which existed between the orbit, the chiasma, and the accessory sinuses of the nose explained the possibility of "nasal blindness."

approved the plans submitted by the Royal College of Surgeons for an important addition to its premises. The extension is to be made to Hill Square and will supply additional accommodation for the museum and provide laboratory and workshop accommodation as well. Various structural alterations have also been approved.

New Medical Superintendent of Larbert Asylum.

Owing to the selection of Dr. G. M. Robertson to succeed Dr. T. S. Clouston at the Edinburgh Royal Asylum, the Stirling district board of lunacy has had to appoint a new superintendent to take Dr. Robertson's place. It has selected Mr. Robert Brown Campbell, M.B., C.M., for the post. Dr. Campbell is a graduate of Edinburgh of 1895 and is at present superintendent of the Inverness District Asylum. He has been assistant in the Crichton Royal Asylum, in the Montrose Royal Asylum, and in the asylum of which he has till now been superintendent.

Glasgow Town Council and Ruchill Hospital.

Another stage in the Ruchill Hospital dispute was reached at the meeting of the Glasgow town council last week. It will be recollected that the troubles were primarily due to overcrowding and understaffing, that the resident physicians, after drawing the attention of the hospitals subcommittee to the existing state of affairs, were dismissed, and that finally a commission appointed by the Local Government Board inquired into the state of matters and found the allegations of the resident physicians to be to a great extent well founded. The next step after the presentation of this finding was that the corporation remitted it to the hospitals subcommittee to consider and report. This proceeding evoked much criticism at the time as the hospitals subcommittee was not considered to have enhanced its reputation by the way in which the whole matter had been handled from the first and many would have preferred to have a special committee appointed. After a series of meetings the hospitals subcommittee, in dealing with the four points at issue, drew up in each case a majority and minority report, and these were presented to the town council last week for approval. As regards the medical officer of health the majority, which numbered ten members, recommended that the statement and explanation of the medical officer of health should be regarded as satisfactory, and stated that he was not implicated in the questions of understaffing and friction. The minority of four, on the other hand, considered that it was his duty carefully to examine the daily returns and to call the attention of the committee to the excessive overcrowding of particular wards. The majority report on this point was accepted by six votes at the corporation meeting. As regards the physician-superintendent, in the majority report it was recommended with the greatest regret that the physician-superintendent should be asked to tender his resignation. The minority recommended that the physician-superintendent should be put on probation for six months. By a majority of three the town council accepted the minority report. In regard to the matron, a majority of the committee recommended that, subject to disapproval of the tone and terms of her "address" to the sisters and staff of nurses, she should be retained. The minority recommended that the matron should be censured for her general want of tact with the nursing staff. By a large majority the majority report was passed by the town council. Finally, in dealing with the dismissed resident physicians, the majority report stated that, without casting any imputation whatever upon their personal character or professional ability, and with the full knowledge that their complaint to the Local Government Board had been largely substantiated by the finding of the commissioners, the committee regretted that they could not recommend their reinstatement. The minority report advised that the dismissed resident physicians should be reinstated subject to their agreeing loyally to obey the regulations imposed upon them by the corporation. By a majority the corporation decided not to reinstate the dismissed resident physicians. The sederunt of the town council lasted continuously for 11 hours and the debate was probably the stormiest on record. Although such has been the finding of the town council the general feeling of the community seems to be that the resident physicians have been hardly treated and that an error in judgment was made by the corporation in remitting the report of the commissioners to be dealt with by the hospitals committee, whose conduct also formed matter for investigation by the commission.

Outbreak of Small-pox in Arbroath.

During the past few weeks there has been a rather serious epidemic of small-pox in Arbroath. Ten cases in all have occurred since the beginning of the outbreak.

Proposed Extension of Aberdeen City Hospital.

The public health committee of the Aberdeen town council in a report on a recent visit to the city hospital, when the wards and nursing staff accommodation were inspected, recommends that a remit should be made to it to report as to the propriety and cost of extending the building so as to meet the growing requirements of the institution.

Ross and Cromarty: Annual Health Report.

Dr. W. Bruce, medical officer of health of Ross and Cromarty, has just issued his annual public health report for that district for the past year. The birth-rate of 21·3 is less than that of last year and shows a very decided fall from that of five years ago. The death-rate was 15·8. Of the deaths, those from infectious diseases amounted to 150 and of these five-sixths were due to tuberculous disease. It is estimated that at present there are 250 cases of consumption in the county. In Lewis the disease is specially prevalent. There were during the year no fewer than 31 deaths from violence, mostly drowning. The infantile death-rate was 92 per 1000 in the Black Isle and 89·8 in Lewis.

Forfar County: Appointment of Medical Officer of Health.

The Forfar County Council met at Forfar on May 7th for the purpose of electing a medical officer of health for the county in succession to Dr. T. F. Dewar who has been appointed to the medical officership of Fifeshire. The Earl of Camperdown presided. There were 11 applications for the vacancy but only two of these were nominated, Dr. Norman J. Sinclair (Brechin) and Dr. A. E. Kidd (Carnoustie). Dr. Sinclair was appointed by a large majority. A letter was read from the Local Government Board stating that it was prepared to allow the new officer to engage in consulting practice. Dr. Sinclair is a native of Aberdeen and a graduate of the University.

Kincardine County Council: Annual Health Report.

The county council of Kincardine met on May 7th, when Dr. W. A. Macnaughton, the medical officer of health, submitted his annual report. This showed that for the year the birth-rate was 23·2 per 1000 and the death-rate 12·9 per 1000. The infantile mortality was 66·5 per 1000. The deaths from tuberculous disease numbered 40, or 1·4 per 1000, the highest recorded for 17 years. Cancer and malignant disease caused four deaths, as against 21 in 1906. One case of cerebro-spinal meningitis was notified and the disease had a fatal result. The death-rate for Stonehaven was 12·9 per 1000, the lowest rate which the medical officer had recorded.

May 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The New University for Ireland.

THERE were published last week the names of the members of the Senate of the new Irish University; those of the members of the governing bodies of two of its constituent colleges now follow. The schedule of the Dublin College, issued on May 9th, contains the names of the members of the first governing body. They are: Denis Joseph Coffey, M.A., M.B., Ch.B. (President); Stephen James Brown; Arthur W. Conway, M.A.; M. F. Cox, M.D.; Rev. William Delany, S.J., LL.D.; Alexander Dempsey, M.D.; Robert Donovan, B.A.; Charles F. Doyle, M.A., K.C.; Miss Mary T. Hayden, M.A.; Hugh P. Lane; J. S. McArdle, M.Ch.; J. A. McClelland, M.A., D.Sc.; John McNeill, B.A.; Henry C. McWeeney, M.A.; William Magennis, M.A.; Right Rev. Monsignor Mannix, D.D.; Joseph Mooney; Sir Christopher Nixon, Bart., M.D.; Charles A. O'Connor, M.A., K.C., First Serjeant-at-Law; Miss Agnes O'Farrelly, M.A.; Patrick J. O'Neill; *Alderman Gerald O'Reilly (the Right Hon. the Lord Mayor of Dublin); Right Hon. Christopher Palles, LL.D., Lord Chief Baron; Patrick Semple, M.A.; George Sigerson, M.D.; and Laurence Ambrose Waldron, M.P. A few others will be proposed. In the case of persons whose names are marked with asterisks it will be proposed that the nomination shall have effect only while they hold the offices a description of which is attached to their names, and that if charm, is a task compared to which the cleansing of the Augean stables was a trifle. No doubt there are appliances which with care and skilful management are effective as to manufacturing smoke and so, perhaps more doubtfully, with domestic fireplaces, but the evil of imperfect combustion has been allowed to grow until it is almost too monstrous to be grappled with. Domestic grates are more difficult to deal with than manufacturing furnaces but the attempt must be made and sometimes, in the case of the well-to-do, it is done with success, but the poor householder is not equal to these things. The injury to commerce and the amenities of life, to say nothing as to the lowering of the vitality of the people, would surely justify some combination of bounties and penalties to aid in attaining to a higher standard of purity in the air which we breathe.

The Port Sanitary Authority and Bad Foodstuffs.

Mr. W. F. Dearden's last official report on the port of Manchester shows that in the month ending April 25th last 225 vessels were inspected and on 90 of them insanitery conditions were found. A great amount of what are somewhat inelegantly called "foodstuffs"—a term indicating an alien origin—now comes up the Ship Canal and requires constant watching. During the month the amount condemned reached a total of 22 tons 4 hundredweights, included in which were 212 bags of onions, which no doubt were in a highly odoriferous condition. So that, accompanying the great benefits which the Canal has brought with it to Manchester, there is the drawback that it renders the town more vulnerable as regards imported disease.

Cotton Districts' Convalescent Fund.

But for the existence of the Cotton Districts' Convalescent Fund the dark days of the cotton famine would be almost forgotten in Lancashire and Cheshire, where the cloud rested so long and heavily. This fund, however, continues to spread abroad its benefits and at the same time to remind those who remember them of the hard times of long ago. During the three months ending March 31st 492 patients were sent to the convalescent hospitals at Southport, Buxton, and Cheadle at a cost of £1134 1*s.* 6*d.*, as against £1161 6*s.* 11*d.* in the corresponding period of 1907, when 477 patients were sent. They were sent from, it may be said, every manufacturing town in Lancashire and Cheshire. Manchester heads the list with 845, Salford sent 216, Bolton 164, and so on till we come to Tyldesley, which contributed 2. The total for 1907 was 1895.

May 12th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Visit of the King and Queen.

To the great gratification of all in Leeds, and notably, of course, to those who are interested in the welfare of the University, the Marquis of Ripon, as Chancellor, has been able to announce that the King and Queen have graciously consented to visit the city to open the new departments of the University. The building operations are now all but completed and comprise an extension of the main building, which will provide adequate accommodation for the arts classes and for the department of botany. A new department for mining and metallurgy has been in operation some time but has not been formally opened. A new wing has been provided for mechanical engineering and a separate block for electrical engineering. Some minor additions of a more or less temporary character are also included in recent efforts. Though it is exactly 50 years since the reigning sovereign has visited Leeds, for Queen Victoria opened the town hall in the year 1858, it must be mentioned that in 1885 King Edward (while Prince of Wales) opened the new buildings of the Yorkshire College and that the present Prince of Wales (while Duke of York) paid a visit to Leeds in 1894 to open the new medical school and the additions to the buildings in College-road.

The University: Changes in the Staff of Demonstrators.

Mr. S. G. Scott, M.A., M.B. Oxon., who has been demonstrator in pathology and bacteriology since 1903, has resigned his position on his appointment as demonstrator of histology in the physiological department of the University of Oxford. During Dr. Scott's residence in Leeds he has acted with much acceptance as honorary secretary of the Pathological Club which was initiated by Dr. E. F. Trevelyan during his tenure of office as professor of pathology. The members of this club, desiring to show their high appreciation of Dr. Scott's work, decided to entertain him to dinner on the occasion of his leaving Leeds. A desire was expressed by some of Dr. Scott's non-medical colleagues on the professorial and demonstrator staff to associate themselves with the members of the club in bidding good-bye to one who has been a favourite with all. Professor de Burgh Birch was in the chair, and among the others who were present were Dr. Bodington, the Vice-Chancellor; Professor A. S. F. Grünbaum, the Dean of the Faculty of Medicine, and many others. Consequent on the resignation of Dr. R. Veitch Clark, who has been appointed assistant medical officer of health to the city, the post of demonstrator of physiology has been filled by the election of Mr. A. Hunter, M.A., B.Sc., Ch.B. Edin. Mr. Hunter has acted as demonstrator in the physiological department of the University of Edinburgh under Professor E. A. Schäfer and during the last two years has held a Carnegie fellowship and has been working at Berlin and Heidelberg on the biochemistry of the proteins.

May 12th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The General Council of the University of Edinburgh.

THE statutory half-yearly meeting of this body was held on May 7th, Principal Sir William Turner occupying the chair. After the minutes of the previous meeting had been adopted the business committee submitted its report. At the outset reference was made to the deaths of Sir Patrick Heron Watson, Professor Thomas Annandale, and Professor A. H. Charteris. Detailed reference was made to Sir P. H. Watson's valuable services as a member of the general council of the University and of the active interest which he took in university matters. The subjects of greatest interest which were dealt with in the report were those of autonomy and the relations of the Universities to the Education (Scotland) Bill, 1908, at present before Parliament. With regard to the question of autonomy, two conferences had been held between representatives of the four Scottish Universities, and these, it was stated, had been useful, and the council decided that they should be continued. As bearing upon this question two memoranda were presented to the council, one of which had been drawn up by Mr. Buchan and submitted to the conference of representatives of the general councils in regard to autonomy. This memorandum pointed out the present position of the Universities and the need of greater freedom. A second memorandum also submitted to the conference was written by Principal A. P. Laurie of the Heriot-Watt College and dealt with the question from other points. Both memoranda were important contributions to the urgent necessity for granting without delay a measure of autonomy to the Scottish Universities at least equal to that enjoyed by the English Universities. At the meeting Sir John Batty Tuke expressed anxiety as to the effect that the Education Bill before Parliament might have upon the Universities—he was afraid that the Scottish Education Department might have too autocratic powers. The report in referring to the Carnegie Trust showed that the Universities during the past five years had received a sum of £200,000 for buildings, for teaching, and for library purposes. An interim scheme of distribution for the period from Jan. 1st to Sept. 30th, 1908, shows a total of £31,228, of which £8750 go to the University of Edinburgh. For the second quinquennial distribution from October, 1908, to September, 1913, the amount reaches £194,000, of which £52,500 go to the University of Edinburgh and £5500 to the Edinburgh Extra mural School. Altogether the outlook for the Scottish Universities is brighter. The number of students is maintained; the Carnegie Trust money has provided much needed help; there is a friendly understanding arising out of the inter-University conferences; and there is the assurance that ere long the Universities will be granted such autonomy as will enable them to develop rapidly along the lines which are so plainly indicated by modern developments in science and in education generally.

Extension of the Premises of the Royal College of Surgeons of Edinburgh.

The Dean of Guild Court of the city of Edinburgh has approved the plans submitted by the Royal College of Surgeons for an important addition to its premises. The extension is to be made to Hill Square and will supply additional accommodation for the museum and provide laboratory and workshop accommodation as well. Various structural alterations have also been approved.

New Medical Superintendent of Larbert Asylum.

Owing to the selection of Dr. G. M. Robertson to succeed Dr. T. S. Clouston at the Edinburgh Royal Asylum, the Stirling district board of lunacy has had to appoint a new superintendent to take Dr. Robertson's place. It has selected Mr. Robert Brown Campbell, M.B., C.M., for the post. Dr. Campbell is a graduate of Edinburgh of 1895 and is at present superintendent of the Inverness District Asylum. He has been assistant in the Crichton Royal Asylum, in the Montrose Royal Asylum, and in the asylum of which he has till now been superintendent.

Glasgow Town Council and Ruchill Hospital.

Another stage in the Ruchill Hospital dispute was reached at the meeting of the Glasgow town council last week. It will be recollected that the troubles were primarily due to overcrowding and understaffing, that the resident physicians, after drawing the attention of the hospitals subcommittee to the existing state of affairs, were dismissed, and that finally a commission appointed by the Local Government Board inquired into the state of matters and found the allegations of the resident physicians to be to a great extent well founded. The next step after the presentation of this finding was that the corporation remitted it to the hospitals subcommittee to consider and report. This proceeding evoked much criticism at the time as the hospitals subcommittee was not considered to have enhanced its reputation by the way in which the whole matter had been handled from the first and many would have preferred to have a special committee appointed. After a series of meetings the hospitals subcommittee, in dealing with the four points at issue, drew up in each case a majority and minority report, and these were presented to the town council last week for approval. As regards the medical officer of health the majority, which numbered ten members, recommended that the statement and explanation of the medical officer of health should be regarded as satisfactory, and stated that he was not implicated in the questions of understaffing and friction. The minority of four, on the other hand, considered that it was his duty carefully to examine the daily returns and to call the attention of the committee to the excessive overcrowding of particular wards. The majority report on this point was accepted by six votes at the corporation meeting. As regards the physician-superintendent, in the majority report it was recommended with the greatest regret that the physician-superintendent should be asked to tender his resignation. The minority recommended that the physician-superintendent should be put on probation for six months. By a majority of three the town council accepted the minority report. In regard to the matron, a majority of the committee recommended that, subject to disapproval of the tone and terms of her "address" to the sisters and staff of nurses, she should be retained. The minority recommended that the matron should be censured for her general want of tact with the nursing staff. By a large majority the majority report was passed by the town council. Finally, in dealing with the dismissed resident physicians, the majority report stated that, without casting any imputation whatever upon their personal character or professional ability, and with the full knowledge that their complaint to the Local Government Board had been largely substantiated by the finding of the commissioners, the committee regretted that they could not recommend their reinstatement. The minority report advised that the dismissed resident physicians should be reinstated subject to their agreeing loyally to obey the regulations imposed upon them by the corporation. By a majority the corporation decided not to reinstate the dismissed resident physicians. The sederunt of the town council lasted continuously for 11 hours and the debate was probably the stormiest on record. Although such has been the finding of the town council the general feeling of the community seems to be that the resident physicians have been hardly treated and that an error in judgment was made by the corporation in remitting the report of the commissioners to be dealt with by the hospitals committee, whose conduct also formed matter for investigation by the commission.

Outbreak of Small-pox in Arbroath.

During the past few weeks there has been a rather serious epidemic of small-pox in Arbroath. Ten cases in all have occurred since the beginning of the outbreak.

Proposed Extension of Aberdeen City Hospital.

The public health committee of the Aberdeen town council in a report on a recent visit to the city hospital, when the wards and nursing staff accommodation were inspected, recommends that a remit should be made to it to report as to the propriety and cost of extending the building so as to meet the growing requirements of the institution.

Ross and Cromarty: Annual Health Report.

Dr. W. Bruce, medical officer of health of Ross and Cromarty, has just issued his annual public health report for that district for the past year. The birth-rate of 21·3 is less than that of last year and shows a very decided fall from that of five years ago. The death-rate was 15·8. Of the deaths, those from infectious diseases amounted to 150 and of these five-sixths were due to tuberculous disease. It is estimated that at present there are 250 cases of consumption in the county. In Lewis the disease is specially prevalent. There were during the year no fewer than 31 deaths from violence, mostly drowning. The infantile death-rate was 92 per 1000 in the Black Isle and 89·8 in Lewis.

Forfar County: Appointment of Medical Officer of Health.

The Forfar County Council met at Forfar on May 7th for the purpose of electing a medical officer of health for the county in succession to Dr. T. F. Dewar who has been appointed to the medical officership of Fifeshire. The Earl of Camperdown presided. There were 11 applications for the vacancy but only two of these were nominated, Dr. Norman J. Sinclair (Brechin) and Dr. A. E. Kidd (Carnoustie). Dr. Sinclair was appointed by a large majority. A letter was read from the Local Government Board stating that it was prepared to allow the new officer to engage in consulting practice. Dr. Sinclair is a native of Aberdeen and a graduate of the University.

Kincardine County Council: Annual Health Report.

The county council of Kincardine met on May 7th, when Dr. W. A. Macnaughton, the medical officer of health, submitted his annual report. This showed that for the year the birth-rate was 23·2 per 1000 and the death-rate 12·9 per 1000. The infantile mortality was 66·5 per 1000. The deaths from tuberculous disease numbered 40, or 1·4 per 1000, the highest recorded for 17 years. Cancer and malignant disease caused four deaths, as against 21 in 1906. One case of cerebro-spinal meningitis was notified and the disease had a fatal result. The death-rate for Stonehaven was 12·9 per 1000, the lowest rate which the medical officer had recorded.

May 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The New University for Ireland.

THERE were published last week the names of the members of the Senate of the new Irish University; those of the members of the governing bodies of two of its constituent colleges now follow. The schedule of the Dublin College, issued on May 9th, contains the names of the members of the first governing body. They are: Denis Joseph Coffey, M.A., M.B., Ch.B. (President); Stephen James Brown; Arthur W. Conway, M.A.; M. F. Cox, M.D.; Rev. William Delany, S.J., LL.D.; Alexander Dempsey, M.D.; Robert Donovan, B.A.; Charles F. Doyle, M.A., K.C.; Miss Mary T. Hayden, M.A.; Hugh P. Lane; J. S. McArdle, M.Ch.; J. A. McClelland, M.A., D.Sc.; John McNeill, B.A.; Henry C. McWeeney, M.A.; William Magennis, M.A.; Right Rev. Monsignor Mannix, D.D.; Joseph Mooney; Sir Christopher Nixon, Bart., M.D.; Charles A. O'Connor, M.A., K.C., First Serjeant-at-Law; Miss Agnes O'Farrelly, M.A.; Patrick J. O'Neill; *Alderman Gerald O'Reilly (the Right Hon. the Lord Mayor of Dublin); Right Hon. Christopher Palles, LL.D., Lord Chief Baron; Patrick Semple, M.A.; George Sigerson, M.D.; and Laurence Ambrose Waldron, M.P. A few others will be proposed. In the case of persons whose names are marked with asterisks it will be proposed that the nomination shall have effect only while they hold the offices a description of which is attached to their names, and that if any such person ceases to hold the office a vacancy will occur to be filled by a further nomination. The names of the first governing body of the Galway College are as follows: Alexander Anderson, M.A., LL.D., President; P. J. Boland, B.A.; Rev. J. C. Clarke, B.A., D.D.; Nicholas W. Colahan, M.D., M.Ch. (Professor); Rev. E. A. Dalton, M.R.I.A.; Very Rev. Canon Daly, D.D.; William Daly, J.P., D.L.; Very Rev. Peter Dooley, P.P.; Joseph Glynn, B.A.; Stephen Gwynn, M.P.; His Grace the Most Rev. John Healy, D.D; John Patrick Henry, M.A., M.D., Ch.B.; Very Rev. Michael Higgins, D.D.; Lord Killanin, D.L.; Richard J. Kinkead, B.A., M.D. (Professor); the Most Rev. J. MacCormack, D.D.; Martin M'Donogh; Rev. T. O. Kelly, B.D.; Right Rev. James O'Sullivan, D.D.; Joseph P. Pye, M.D. (Professor); Alfred Senier, Ph.D. (Professor); Valentino Steinberger, M.A. (Professor); Edward Townsend, M.A., D.Sc. (Professor); and Wilbraham F. Trench, M.A. (Professor). Another person or persons will be proposed. The conspicuous representation of the medical profession on the governing body of the Dublin College augurs well for the position which is to be taken by its Faculty of Medicine and its influence in the University's policy. Dublin is able to furnish an exceptionally strong list of medical men well qualified to hold office in this capacity. The medical school which in the past produced Stokes and Graves can in the present generation boast of the scholarly and scientific attainments of Cox and Sigerson; while the brilliant public as well as professional career of Sir Christopher Nixon brings to mind that of Sir Dominic Corrigan, since whose day he has been the first Irish medical man to receive the honour of a baronetcy.

Irish Medical Association: New President.

The Irish Medical Association has just elected Sir William J. Smyly as its new president. If popularity be the true test of merit no more worthy choice has ever been made in the selection of a chairman for that body. But the whole professional record of Sir William Smyly is one of high-class work as a practitioner, as an organiser, as a teacher, and as a contributor to the scientific literature of his profession, as well as an exemplary leader and guide of his professional brethren in the very cleanest pathways and along the lines of the best and highest professional traditions. In all these respects he is a thoroughly worthy successor of Mr. J. S. McArdle whose aims and attainments have always been along closely parallel lines of professional advancement, with the most jealous conservation of professional honour, truthfulness, and dignity. And I am glad to see, though others may think proper to criticise the feature with less favour, that social gatherings are from time to time to form one of the specially distinctive features of the *régime*. Our old customs are changing rather too fast as it is and some of us would fain cling to some surviving links of our proverbial national hospitality.

The Election of a Medical Officer by the North Dublin Board of Guardians.

The North Dublin board of guardians recently appointed Mr. C. Casey to the vacant medical officership of No. 2 Dispensary District, an election to which the Local Government Board took objection. This was discussed energetically at a recent meeting of the guardians at which a letter was read from Dr. Thomas Donnelly, who has served them for 24 years, complaining that he had been passed over for the appointment in the face of their own regulations as to promotion by seniority. After one guardian had warmly urged the meeting to defy the Local Government Board and ratify their first election the discussion was postponed. Dr. Donnelly has a brilliant career behind him and the qualifications of M.D., M.A.O. Dub., F.R.C.S. Irel., and D.P.H. It is unlikely in the extreme that a more suitable candidate will apply for the post.

The Workman's Compensation Act.

On May 5th the Recorder of Dublin heard a claim under this Act by Catherine Doyle against the governors of Steeven's Hospital. She had injured her thumb when working in their employment and "blood poisoning" had ensued which necessitated a subsequent operation. She alleged that this was due to neglect on the part of the hospital authorities, which was denied by Mr. Good on their behalf. The applicant swore that she had complained to the matron of the hospital at the time of the accident which that lady denied. The matron heard subsequently that the applicant had been pricked by a fish-bone. His lordship, in commenting on the case, said that the matron had given very candid and proper evidence and that it was a pity that information of the accident had not been given earlier to the authorities of the hospital, but that it was quite plain that it had occurred. A great deal of trouble had been unnecessarily thrown upon the authorities of this hospital, which subsisted on charity and was constantly relieving the poor, by the want of proper notice. He was compelled by statute to grant costs, which he would fix at £3 3*s.*, and would award the applicant a small amount—£2 10*s.*

The Sanitation of Ballina.

The western town (or village) of Ballina has for some time been establishing for itself a most malodorous reputation in sanitary matters. On April 20th a meeting of the Ballina board of guardians was held and the medical officer's report contained the following paragraph:—

> Since last report five cases of fever were admitted; remaining 17; no deaths. Such a large number of fever cases with an extra fever nurse entails considerable expense to the ratepayers. If for no other consideration the sanitation of the town and district ought to claim some of your attention.—R. MACAULAY.

No order was made on the report and there appears to have been no discussion on the reading of it. The Ballina council discussed the report on April 21st in association with the sanitary condition of the town. Two reports have lately been submitted to the urban council on the subject: one of these was made by a committee of the council and the other by Sir James Acheson MacCullagh. Not long ago there was a sharp outbreak in Ballina of an epidemic of typhus fever. Reports were then prepared regarding the appalling state of the sanitation of the town and its vicinity. Some superficial cleansing was carried out under the influence of this stimulus; but, too like the methods of the old-time Hibernian traditions, the local arrangements were soon allowed to drop back into their old happy-go-lucky methods, with their dirt and apathy and passive expectancy. Ever since the place has been infested with fevers of various kinds: typhus fever, diphtheria, scarlet fever, &c. There is surely need of some increase of sanitary activity.

Ulster Medical Society.

An adjourned meeting of the Ulster Medical Society was held in the Medical Institute, Belfast, on May 7th, to discuss a series of motions framed by the committee appointed to consider the question of hospital abuse. Owing to the very small attendance it was decided to adjourn the discussion of the motions until next session.

Londonderry Eye, Ear, and Throat Hospital.

At the annual meeting of the friends of this hospital, held on May 6th, it was reported that during the past year there were 1293 dental extern patients and 1321 eye, ear, nose and throat cases. There were 112 intern cases. Financially the total income for the year was £336 2*s.* 2*d.*, as compared with £385 0*s.* 8*d.* for the previous year, while the expenditure had increased from £263 5*s.* 1*d.* to £347 8*s.* 8*d.*

Medical Benevolent Society of Ireland.

At the annual meeting of the Belfast and co. Antrim Branch of the Royal Medical Benevolent Fund Society of Ireland, held in the Medical Institute, Belfast (Professor J. A. Lindsay, the President, being in the chair), on May 8th, it was reported that the whole amount to the credit of the branch was £155 14*s.* 6*d.*, being 2 guineas less than last year, as follows: £99 5*s.* subscribed by 146 medical practitioners in Belfast, £26 7*s.* 6*d.* forwarded by 39 country practitioners, besides £15 per Dr. J. C. Martin of Portrush, collected at the annual dinner of the Irish Medical Association; £2 11*s.* 6*d.* from the Ulster Medical Society, and 6*s.* interest on deposits. 14 sympathisers outside the medical profession subscribed £12 4*s.* 6*d.* Professor J. Symington was elected president for the ensuing year.

May 12th

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Relapsing Fever in Tonkin.

A SEVERE epidemic of relapsing fever has broken out at Cam-Ly and an enormous loss of life has occurred among the Annamites. In one village, for instance, which formerly contained over 200 inhabitants, there are now barely 80, and with the exception of two or three all these deaths are due to relapsing fever. The authorities of Phu-Lang-Thuong have taken active steps for preventing the spread of the disease which is due in great measure to the concealment of cases by the headmen of the infected villages. A hygienic commission is to be (*doit être*) established at Phu-Lang-Thuong immediately charged with the duty of imposing most rigorous hygienic measures upon the inhabitants.

Cacodylate of Sodium and Arrhenal in the Treatment of Corneal Ulceration.

Madame Bonsignorio read a paper at the April meeting of the Therapeutical Society upon the results which she has obtained during the last two years in the treatment of all kinds of corneal ulceration and of ulcerative blepharitis with cacodylate of sodium. She uses this salt either in a 3 per cent. solution or in a 2 per cent. ointment, and arrhenal as a 3 per cent. solution. Under this treatment the ulcerations heal up rapidly. In the treatment of ulcerative blepharitis care must be taken to remove the crusts by bathing with warm water before the application of the cacodylate ointment. The edges of the eyelids are smeared every evening with this ointment for eight days, and then for eight other evenings at an interval of every other day. The application of the ointment brings about a slight smarting which only lasts for two or three minutes. In the case of corneal ulceration a small quantity of the ointment is placed in the eye when the patient goes to bed.

Reforms in Medical Education.

Since the beginning of 1907 a committee appointed by the Ministry of Public Instruction has been sitting to consider what modifications in medical studies it may be desirable to effect. Last month the committee issued a report consisting of a series of resolutions, of which the following are the chief. The future medical student should have an education which is intellectual, literary, and philosophical. The preliminary scientific examination should be specially directed towards the future application of its subjects to medical study. The committee insists upon the retention of all the subjects of instruction which have been laid down since 1899, but it is of opinion that there should be added to these as compulsory subjects instruction in practical midwifery, dermatology, venereal diseases, diseases of the urinary organs, nervous and mental diseases, medical and surgical diseases of children, ophthalmology, and oto-rhino-laryngology. Gynæcology will not be an obligatory subject. The committee also considers that instruction should be given in stomatology. The committee rejected the proposal of a sub-committee that instruction should be given in social medicine, but proposed in its place that instruction should be given in jurisprudence (*législation*) and in deontology. The duration of the curriculum is five years, which term, however, does not include the first year. The committee is of opinion that medical students should not be allowed to reckon their class attendance during the time of their military service. No retrospective or cumulative class attendance will be allowed except on proof of knowledge as shown by examination (*stage*) and practical work. The committee is of opinion that a curriculum of professional instruction should be definitely formulated. There should also be opportunities for obtaining advanced instruction both for students desirous of increasing their knowledge and for practitioners wishing to keep themselves up to date. Attendance at such course would be optional. Professional instruction is given at the Faculty so far as theory goes, and this system ought to be continued. But the nature of the teaching ought to be modified by the addition of technical instruction in laboratories provided with proper teachers and appliances, just as in hospitals clinical instruction is given in the wards. The committee passed a resolution calling upon the Government to find ways and means for providing the Faculty and schools with material for practical teaching, which is indispensable to the study of medicine, in order to bring about if possible appropriate Government grants and in every case the coöperation of the various Government departments concerned. The committee further demands that in examinations marking by ballot should be done away with. The marks should only be given after due deliberation. The following marks are to be given:—*Extrêmement satisfait, Très satisfait, Bien satisfait, Satisfait, Mal, Nul.* The marks *Mal* and *Nul* mean rejection. In clinical examinations *Mal* means that the student is to be referred for three months and *Nul* for six months. If a student is referred for a second time he is to be referred for six months.

Iodism and Purgatives.

A case reported by M. Ramond to the Hospitals Medical Society on May 1st shows the necessity in some instances of caution in the use of purgatives. The patient was a woman, aged 56 years, who was in the habit of taking purgatives which, as a rule, produced no inconvenience. Ordinarily, too, she was able to take iodides without any symptoms of iodism. But if when under the iodide treatment she also took a purgative she very shortly showed symptoms of acute iodism, such as coryza, headache, and even a scarlatiniform rash accompanied by itching.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Post-graduate Lectures in Vienna.

THE Vienna Aerzte-Kammer (Medical Council) has arranged with the professors of the clinics to give a series of post-graduate lectures at very low fees during the months of May and June to all medical men who may wish to attend them without restriction as to numbers. The courses will consist of from four to eight lectures and for graduates of the University of Vienna the fees are only from 2*s.* to 4*s.*, whilst holders of qualifications obtained from other sources pay from 5*s.* to 10*s.* The subjects include diphtheria, disorders of metabolism, hæmatology, the serum reaction in syphilis, and diseases of children. If the number of applicants should be large enough to encourage a repetition of this experiment the intention is to have such classes every three or four months. The fees paid will be handed over to the Society for the Relief of the Widows and Orphans of Medical Men.

The Dangerous Stage of Enlarged Prostate.

Dr. Götzl, in a paper read before the Society of German Practitioners, summarised the results of an extended series of researches on the dangers of the last stage of prostatic enlargement. He said that it was characterised by ischuria paradoxa, polydipsia, polyuria, and painless distension of the bladder; if the bladder was evacuated too quickly severe hæmorrhage might follow after a few hours. The prognosis was bad if the condition was not relieved soon, as toxæmia and sepsis (or, as the author of the paper called them, urosepsis and urotoxæmia) were liable to ensue. Extreme distension of the bladder was often misinterpreted by the patients who did not give so much attention to it as to disturbances of the alimentary canal, and in this way the medical attendant might be sometimes misled. The mortality has been computed at 45 per cent., proving that a correct diagnosis and immediate interference were required. Infection was often caused by hasty catheterisation, and if the distension of the bladder with the secondary stasis in the kidneys persisted for a long time pressure atrophy of the latter might follow with a fatal result. Dr. Götzl has observed 288 cases of serious consequences of hypertrophy of the prostate. The age of the patient was of little significance, the youngest being 54 years and the oldest 81 years of age. Careful examination was the only means of arriving at a correct diagnosis.

Migraine and X Rays.

In a paper communicated to the Neurological Society by Dr. Schüller and Dr. Hirschl the cause of some attacks of migraine was explained by the presence of definite changes in the bony capsule of the brain. In both of the cases described children were victims to periodical attacks of intense unilateral headache. In one patient, who was a boy, 11 years old, an x-ray photograph showed the characteristic changes of hydrocephalus, and further inquiry resulted in the disclosure that parental syphilis was extremely probable. The other patient, a boy, aged seven years, showed a very marked degree of the impressiones digitatæ, the skull having in some places been rendered as thin as paper by the pressure. He also showed early ossification of the coronary sutures and his attacks were readily explained by constant intracranial high pressure.

Operation for Atresia of the Choanæ.

Dr. Harmer at a recent meeting of the Laryngological Society showed a patient, aged 20 years, whose condition presented several remarkable features. When first brought under observation nine years ago many polypi had to be removed from the left side of the nose, after which complete osseous atresia of the left choana was found and much trouble was required to perforate the bone with a strong probe and to push a drainage-tube through this aperture.

By increasing the thickness of the tubes this aperture was subsequently enlarged, but it closed again when the treatment was discontinued for a year and the whole process had to be repeated until a medium-sized tube could be forced through. Dr. Harmer then chiselled away the bone along the periphery of the aperture until the latter was of the size of a man's thumb. During five months wicks of iodoform gauze of the size of a large hazelnut had to be pushed from behind through the aperture every day until it remained stationary for a few weeks, so that it might be assumed that the tendency to form fresh bone has now been overcome. As a rule, operations for atresia of the choanæ were not very pleasant and the result was not always gratifying to either the surgeon or the patient. The plan of chiselling the bone away was perhaps the best and most efficient one of all those known at present.

The Antagonism of Poisons.

At a recent meeting of the Vienna Gesellschaft der Aerzte Professor Horst-Meyer spoke on the important subject of the antagonistic action of poisons introduced into the organism. He discriminated between an absolutely chemical antagonism and a physiological antagonism and said that the experiment on the animal must show the true nature of these opposing actions. In the chemical group the poison and the antipoison combined to form an indifferent body, whereas in the second group the poison and the antipoison acted upon an organ independently of each other but with opposite results and had no mutual interaction. For instance, atropine paralysed the non-striated muscles and the heart, while pilocarpine stimulated them. In some cases the poison acted on the central nervous system, examples of this kind being afforded by morphine, prussic acid, caffeine, and picrotoxin. Some poisons lowered the temperature of the body, while some raised it. Then there was a third group of poisons which acted upon groups of physiologically antagonistic organs. Thus the sympathetic nerve was antagonistic to some cerebro-spinal nerves. The cranial and sacral independent nerves were stimulated by pilocarpine and paralysed by atropine, whilst the sympathetic nervous system was not influenced by these substances. On the other hand, the sympathetic system was stimulated by adrenalin and cocaine, whilst codeine paralysed it. An organ controlled by both these nerve groups could be influenced by different poisons in an antagonistic way: thus the blood-vessels were contracted by pilocarpine and dilated by adrenalin or cocaine if the corresponding nerves have been poisoned by substances antagonistic to these. Little was at present known as regards the correlative actions of the internal secretion of the thyroid, adrenal, pancreatic, and sexual glands.

Health of Vienna.

The statistical figures for the last two months show that, although the morbidity of the city has been increasing, the mortality has declined in a satisfactory degree. The majority of the increases of disease is due to infectious conditions, inflammations, and infantile diseases. Measles was a well-marked feature of all the last reports. The sudden changes of the weather caused also many cases of bronchitis and pneumonia. Only one case of enteric fever was reported, but many cases of scarlet fever and measles occurred every week. A remarkable decrease of deaths due to neoplasms and tuberculosis has been observed during the last four months, but the fact cannot be explained as yet. The mortality from diphtheria has been constantly kept below 8 per cent., thanks to the absolutely strict adherence to Behring's teachings, enforced by the Vienna Board of Health.

May 11th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Pancreatic Disease Treated with Pancreatin.

Mr. Gedeon Richter, a chemist, has been investigating the effects of the administration of various organic products in a series of cases where disease of the pancreas was believed to be present. As thyroid extract is successfully administered in diseases of the thyroid gland he thought it probable that similarly good results might be obtained with pancreatic extract in disturbances of the pancreatic functions. A medical man who was associated with Mr. Richter in the inquiry considered that a diagnosis of pancreatic disease might be made when the patient suffered from pancreatic colic, disturbances of metabolism and digestion marked by the appearance of sugar in the urine, fatty stools, and diminished absorption of albuminoid substances. Among the various remedies which were tried they found that thyroidin exerted an unfavourable influence on the symptoms. Pancreon had little effect on the absorption of nitrogen and none at all on the fat. When pancreatin was used, however, the absorption of nitrogen was increased from 52 to 56 per cent. and the absorption of fat from 38 to 60 per cent. These favourable results were enhanced by the simultaneous administration of large doses of the alkaline carbonates but the use of the latter alone was not attended by any improvement. The best combination was a mixture of pancreatin and sodium bicarbonate.

Alcoholism and Arterio-sclerosis.

Dr. Révész of Nagyvarad in a recent discussion on the subject of alcoholism and arterio-sclerosis said that there was a universal consensus of opinion in literature to the effect that alcohol was the most prominent factor in the production of arterio-sclerosis. All the text-books on general medicine, and especially the text-books on diseases of the heart and arteries, agreed in this. There were, however, some sceptics. It was important to supply definite answers to the questions, What is alcoholism, and what is arterio-sclerosis? As regards the latter question, he believed that all cases should be excluded in which the radial artery was merely palpable but not tortuous or hard. At different hospitals a number of necropsies of patients with palpable arteries have been recorded without any changes being present that could be called arterio-sclerotic. Alcoholism would surely be considered to be present in extreme cases in which patients have consumed large amounts of intoxicating beverages for long periods of years. At various institutions in Hungary where chronic alcoholics were admitted Dr. Révész has secured the results of necropsies. Many of these individuals had been accustomed to take a litre of brandy a day. There was no doubt of the reality of the alcoholism in these cases. About 50 were excluded because of the evident presence of syphilis. In only 18 out of nearly 300 cases—i.e., in only about 6 per cent. of the whole—was there arterio-sclerosis of the peripheral vessels. Of course, all patients were excluded who were over 50 years of age. If the patients over 40 years of age were also excluded there remained only four patients—i.e., no more than 2 per cent. of the whole—suffering from arterio-sclerosis in confessed alcoholic cases.

Cardiac Symptoms in Anæmia.

Dr. Berkovics delivered an address on the subject of Cardiac Symptoms in Anæmia at a meeting of the Medical Society of a provincial town in Hungary. He said that the most interesting feature of pernicious anæmia was the slight amount of cardiac disease which existed in connexion with extremely marked pathological conditions of the blood. Even hard workers did not complain much of their hearts, nor, except for a certain amount of dilatation, were there any concomitant physical signs. Murmurs arising from the altered condition of the blood existed very often, but they were not as common as in chlorosis. They were to be found over the large vessels and accompanying the systolic sound of the heart. They changed very much with variations in the conditions of the patient's blood and might even disappear during intermissions of the disease. Since Dr. Billings of America had called attention to the fact that spinal symptoms were common in connexion with pernicious anæmia Dr. Berkovics has seen three cases which supported the observation made by Dr. Billings. Dr. Stockton has described nine cases in all of which spinal symptoms were associated with pernicious anæmia. In such cases dyspnœa was the most important symptom. Cases of the disease were often overlooked and it was not unusual for patients to come seeking advice under the belief that they were suffering from cancer of the stomach, disorder of the liver, disease of the heart, or locomotor ataxia.

The Toxic Agent of Cholæmia.

Dr. Landauer, writing in the *Orvosok Lapja* on the toxic agent of cholæmia, says that icteric patients sometimes develop an alarming series of cerebral symptoms which usually end in coma and death. The direct cause has frequently been a matter of speculation and it is as yet undecided whether the bile pigments, bile acids, or the loss of hepatic function are at fault. Dr. Landauer noticed a close resemblance to diabetic coma and concluded that the whole condition is an acid intoxication. The common bile-duct was ligatured in a number of rabbits and the blood was tested every day until death which generally occurred on the fifth or sixth day. The alkalinity gradually diminished day by day, but not to a sufficient degree to account for the symptoms on the basis of an acid intoxication. The amount of carbon dioxide was also found considerably below the normal. Since animals with much less alkali in their blood have been known to live for days it is probable that other factors are responsible for the fatal termination.

May 7th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Sanatoriums for Consumptives.

THE Victorian Sanatorium for Consumptives has hitherto been conducted on a dual system of paying and non-paying patients. The Inspector of Charities has recommended that the Government grant should be only continued on condition that certain rules of the institution are abolished. The rules objected to provide that all patients must pay their travelling expenses to and from the sanatorium and for washing while there; that separate accommodation must be provided for paying patients; that patients must possess certain articles of clothing; and that, unless unfitted by illness, each patient must be present at evening prayer. A medical superintendent has been appointed and in future only trained nurses will be employed. It is proposed that the name should be altered to the Macedon Sanatorium. The Premier has approved the recommendations.

Opium Traffic.

In December, 1905, the Federal Government made a proclamation in respect to prohibition of opium importation. The Controller-General of Customs has issued a report showing that it is very doubtful whether it has lessened to any great extent the amount of opium introduced. The report says, *inter alia*, "The official statistics show that the quantity of smoking opium imported in 1905 (the last year it was allowed) was 47,118 lb. The smoking of opium—that is, to any great extent as a general habit—is limited almost entirely to the Chinese population. This is estimated to number something under 26,000 in the whole of the Commonwealth. Of this number I am assured by our detectives that not more than a quarter are habitual opium-smokers. This would mean that there are 6000 or 7000 Chinese who use the drug in Australia. ...... Owing to the total prohibition the price of opium has risen enormously, ... a smoke costing 2*s.* 6*d.* The Commonwealth gladly gave up £60,000 revenue with a view to the suppression of the evil, but the result has not been what was hoped for. The gains are so enormous that others beside Chinese have been tempted to enter into the trade and so the chances of detection are greatly decreased.......What is necessary is a Commonwealth enactment that the mere possession of opium by any person on arrival in Australian jurisdiction shall be a penal offence, and State legislation to enact the same for possession within a State and for the use of the article in smoking.......The great bulk of the opium smuggled from the East is hidden in the coal of the steamers arriving. ......It was only the other day that a well-dressed woman, unexceptionable in appearance, was known to be going on board a steamer with a view to bringing opium ashore and to that end had a petticoat provided with large pockets in which to slip the tins. She was arrested and searched but the pockets were found empty, and she explained she had been disappointed."

Record Find of Plague Rats.

Although only two or three cases of plague in human beings have been reported in Sydney during the last three months plague rats continue to be discovered in various parts of the city. Recently a record find was made under a produce store in Sussex-street. No fewer than 38 rats, dead or dying from plague, were discovered at this establishment.

Inebriate Returns.

In July, 1907, a Government hospital for inebriates was opened at Lara, near Melbourne. In a report by Mr. W. Jones, the official inspector, it is shown that during the first six months of its existence 26 patients were received and 13 of these were allowed out on probation. Three were discharged and only one relapsed. 22 of the 26 were "regular" inebriates. The cost during that period (including purchase and alterations) was £10,550. Receipts amounted to £371 and salaries and maintenance totalled £957. Mr. C. G. Godfrey, the visiting medical officer, says: "It is apparent that some plan will have to be adopted to alter the present system of admitting indiscriminately all kinds of cases. It must be recognised that this institution, equipped only as a sanatorium, cannot successfully be used at the same time as a reformatory or as a place for detention of incurable cases or as a means for punishing wilfully vicious alcoholics. Experience has already shown that it is most undesirable and productive of harm to associate the discontented, especially those who have been sent to the institution against their will, with those cases anxious for recovery and carrying out their treatment cheerfully. The question of dealing with objectionable and wilfully insubordinate patients has already arisen. Under the present regulations there exists no means of punishing such conduct except by expulsion, which may be the object at which the patient aims. There is no obligation on the part of the patient to work. There is no power to compel him to do so." Dr. Godfrey thinks that it will be necessary to establish separate institutions for (1) voluntary and requitable cases; (2) inebriates unwilling to be cured but detained for treatment; and (3) irreclaimable inebriates and those of the vagrant class.

April 7th.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following candidates have passed the Third M.B. examination, Part II.:—

G. D. Alexander, Caius; H. T. Ashby, Emmanuel; J. H. Board, Pembroke; J. R. Briscoe, H. Selwyn; L. B. Cane, King's; G. G. Collet and T. R. Elliott, Trinity; E. G. Fearnsides, Trinity Hall; H. G. Frean, St. John's; B. C. Ghosh, St. John's; P. Hall-Smith, Pembroke; C. H. Ilott, Caius; R. L. Ley, Pembroke; H. N. Little, Caius; W. B. Marshall, St. John's; A. J. May, Sidney-Sussex; J. B. Mennell, Pembroke; H. E. B. Oakeley, St. John's; M. Phillips, Caius; K. Pretty, King's; R. C. Priest and K. D. Pringle, Caius; M. R. Sawhny, Downing; L. W. Sharp, Caius; R. W. S. Walker, Trinity; E. G. Wheat, Christ's; C. E. Whitehead, Caius; and J. F. Windsor, H. Selwyn.

The following candidate has passed the M.C. examination:—

H. T. Gray, Trinity.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the President, Vice-President, and Council held on May 5th the following examiners were elected for the ensuing year:—Court "A"—Anatomy: Mr. Alexander Fraser and Dr. Bertram C. A. Windle. Surgery: Mr. Charles A. K. Ball, Mr. Alexander Blayney, Mr. E. Conway Dwyer, and Mr. Robert J. Harvey. Physiology and Histology: Mr. Denis J. Coffey and Mr. E. L'Estrange Ledwich. Pathology and Bacteriology: Mr. Arthur Hamilton White. Midwifery and Gynæcology: Dr. Frederic W. Kidd. Biology: Mr. John J. Burgess. Ophthalmology: Mr. Arthur H. Benson and Mr. Herbert H. B. Cunningham. Sanitary Law and Vital Statistics: Mr. Edward Francis Stephenson. Engineering and Architecture: Mr. James H. Fergusson. Languages: Mr. Latham J. Woodroffe. Mathematics, Physics, Dictation, and English: Mr. John W. Tristram. Court "B"—Anatomy: Mr. Patrick Joseph Fagan and Mr. Alexander Fraser. Surgery: Mr. Charles A. K. Ball, Mr. Alexander Blayney, Mr. E. Conway Dwyer, and Mr. Leveson-Gower Gunn. Physiology and Histology: Mr. Denis J. Coffey and Mr. E. L'Estrange Ledwich. Pathology and Bacteriology: Mr. Robert J. Rowlette and Mr. Arthur Hamilton White. Midwifery and Gynæcology: Dr. Frederic W. Kidd. Chemistry and Physics: Mr. Edwin Lapper and Mr. Robert J. Montgomery. Dental Surgery and Pathology: Mr. George M. P. Murray and Mr. William G. Story. Mechanical Dentistry: Mr. Daniel L. Rogers and Mr. Edward Sheridan.

THE LATE MR. CHARLES EDWIN LAYTON.—Mr. C. E. Layton, whose death occurred on April 29th, at his residence, 17, Cornwall-terrace, Regent's Park, at the age of 65 years, was well known to the medical profession in his capacity of a generous and discriminating supporter of charities. He was until 1897, when he retired, a member of the firm of Charles and Edwin Layton, printers and publishers, of Farringdon-street, and was a director of the old New River Company and of the company of the same name which was formed to manage the properties not taken over from the old company on the formation of the Water

Board. On his retirement from active business he devoted much of his time and thought to philanthropic work, especially in connexion with the various charities connected with the Haberdashers' Company. He was an Associate of King's College, a member of the house committee of St. Bartholomew's Hospital, upon the council of King's College Hospital, and a vice-president of the Royal National Hospital for Consumption, Ventnor. Amongst other institutions with which he was prominently connected were the Corporation of the Sons of the Clergy, the Poor Clergy Relief Fund, and the Metropolitan Hospital Sunday Fund. He was also a generous supporter of the charities in connexion with the publishing trade.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—A quarterly meeting of the Royal College of Physicians of Edinburgh was held on May 5th, Dr. J. Playfair, Vice-President, in the chair. The Vice-President at the beginning of the meeting referred to the great loss which the College had sustained in the death of the President, Dr. C. E. Underhill, and submitted a minute of sympathy, which was adopted and sent to the relatives. Dr. George Douglas McRae and Dr. Harold Sherman Ballantyne were introduced and took their seats as Fellows of the College. Dr. George Herbert Rae Gibson, M.B., Ch.B., Edinburgh, and Dr. Thomas Goodall Nasmyth, M.D., D.Sc., D.P.H., Edinburgh, were admitted by ballot to the Membership of the College. The registrar reported that since the last quarterly meeting 34 gentlemen had obtained the Licence. The curator's report regarding the research and reporting work undertaken in the laboratory during the last year and the expenditure incurred was submitted. The report showed that 33 workers had been engaged in research, that 3022 specimens had been reported on, being an increase of 291 on the number for the previous year, and that the expenditure had amounted to £1060. The report was adopted by the College. Dr. Norman Walker was re-elected as representative of the College on the Conjoint Committee of Management of the Triple Qualification. Dr. Frederick W. Mott was appointed Morison lecturer for the ensuing session.

THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.—The festival dinner of this charity was held at the Trocadéro Restaurant on May 12th, Mr. H. Robertson, chairman of the house committee, being in the chair. Covers were laid for about 200 guests and the proceedings were marked with much enthusiasm. It is now 60 years since the hospital commenced its work in Liverpool-street in the heart of the East End, and it is attended by enormous numbers of poor people. Since the foundation of the hospital 40,317 in-patients have been admitted to the wards and 737,978 out-patients have attended the out-patient department. The toast of "The Medical Staff" was proposed by Mr. F. Brinsley-Harper who referred to the great work of Lord Lister and described in eulogistic terms the services of the medical officers of the institution. This toast, which was honoured with musical honours of the heartiest and loudest character, was replied to by Dr. G. A. Heron who described the success that had attended the dental department: more than 700 patients had received advice, there had been 400 administrations of gas, 1600 extractions of teeth under anæsthesia, and 300 extractions without anæsthesia. The chairman proposed the toast of "Prosperity to the City of London Hospital for Diseases of the Chest" and emphasised the fact that the hospital was largely supported by subscriptions from the working classes. The secretary then announced that the subscription list amounted to £2081. Sir M. M. Bhownaggree proposed "The Honorary Officers and Executive Staff," which was responded to by Mr. F. Hyland. Dr. E. C. Beale having submitted the toast of "The Chairman," to which a suitable reply was made, the proceedings terminated.

LITERARY INTELLIGENCE.—Mr. H. K. Lewis has just issued the fourth edition of "Public Health Laboratory Work" by Professor H. R. Kenwood, of University College, London, and has ready for immediate publication the sixth edition of Dr. William Murray's "Rough Notes on Remedies," which will contain the address recently delivered before the Royal Society of Medicine, together with other new matter. The same publisher will also issue Professor Ehrlich's Harben Lectures on "Experimental Researches on Specific Therapeutics," which were delivered at the Royal Institute of Public Health in 1907, and a book on "The Extraction of Teeth" by Mr. Frank Coleman.—Messrs. Spottiswoode and Co., Limited, are about to publish by subscription a volume dealing with the leaving portraits in the Provost's Lodge at Eton College, which may be of interest to some of our readers. The College possesses a series of portraits of boys painted by the master-hands of Reynolds, Gainsborough, Lawrence, Romney, Hoppner, West, and Beechey, 100 of which will now be reproduced by photogravure, together with a catalogue of the whole series. Further particulars may be had by applying to the publishers at 5, New-street-square, London, E.C.—A second edition of the "System of Midwifery," by Dr. T. W. Eden, is just ready. It will contain about 50 more pages, 16 additional plates, and other new illustrations. To meet the needs of army officers, who are now required to pass examinations in sanitation and hygiene, Lieutenant-Colonel R. H. Firth, R.A.M.C., has compiled a small book on Military Hygiene. The text will be illustrated by original drawings. Both of these books will bear the imprint of J. and A. Churchill.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Gustav Guldberg, professor of medicine in the University of Christiania, at the age of 54 years. His published works deal mainly with anatomy, both human and comparative. He wrote much on the anatomy of cetaceæ.—Dr. Karl Breitenbach of Aschaffenburg.

THE ROYAL SANITARY INSTITUTE.—The dinner of the Royal Sanitary Institute took place this year at the Langham Hotel on May 12th and was the occasion for the delivery of several interesting, amusing, and encouraging speeches. The Duke of Northumberland, K.G., presided, and he was able to announce that the institute now numbered 3700 members, that it possessed a capital of £17,000, and that the revenue last year amounted to £7857. They had held 579 meetings and had addressed probably some 22,000 people. The examinations concerning hygiene in its bearings on school life formed a recent innovation that was likely to prove of great help in carrying out the medical inspection and sanitary control of school children. But the most important fact, so far as the interests and usefulness of the institute are concerned, is the hope entertained that it will be able to remove at an earlier date to more suitable premises. These will be in the neighbourhood of Victoria Station and will supply double the present accommodation. Lady Douglas Galton has subscribed £100 towards the cost of these premises and it is proposed to name a section of the new muesum the "Douglas Galton Gallery." Mr. Justice Grantham gave a very humorous sketch of the legislature, comparing the House of Commons to a younger brother who was ever drawing at sight on his elder brother the House of Lords, till the latter at last refused to honour the bills. Thus we had been promised a big fight between the two, but after all, and at the last moment, the younger brother had "knocked under," so perhaps we should have some useful legislation after all. Lord Robert Cecil, M.P., was also sarcastic and amusing, remarking that after having a big row in the House the rival parties went to the law courts to see what they had done and then generally discovered that the law which they had passed was what neither of them had intended. But now, however, that the Board of Agriculture and Fisheries was to decide on town planning we might hope for more coherence! Though the majority of the present House was not to his liking he must say that there had been some very excellent sanitary legislation. Sir Shirley F. Murphy in his speech found fault with the Port of London Bill because it placed the control of the upper reaches of the Thames in the hands of the very people who pollute the water. In regard to legislation, the President drew attention to the fact that there was an alteration in the methods of sanitary progress. Formerly people believed in decentralisation and thought the work would be best done by small local bodies. Now it was felt that these bodies neglected to apply the laws. What was most needed was not fresh sanitary laws but a more rigorous application of the existing laws. Therefore it might be wise to give larger powers to the county councils. Where, however, the central government had to interfere it ought not to have the right to impose a local rate. Sir R. Douglas Powell, President of the Royal College of Physicians of London, summed up the whole situation in regard to the Royal Sanitary Institute by saying that if it continued at its present rate of progress the time was fast approaching when the physician will no longer be able to live or to die.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

New-born Children (Protection) Bill.

THE order for the second reading of the New-born Children (Protection) Bill has been discharged in the House of Commons and the Bill withdrawn.

The Children Bill.

One of the Grand Committees of the House of Commons has been dealing with the Children Bill and considerable progress has been made with it. The recommendations of the Select Committee which recently reported on the notification and inspection of homes in which infants are nursed and maintained in consideration of reward have been adopted and embodied in the first part of the Bill. The effect of the changes in the Bill is to extend the notification and inspection instituted under the Infant Life Protection Act, 1897, to "one-child homes" and to raise the age limit of the children who are the subject of inspection from five to seven years. Mr. HERBERT SAMUEL, the Under Secretary for the Home Department, who has been in charge of the Bill, has consented to give full consideration to amendments dealing with the particulars to be given in the notification to the local authorities before the report stage of the measure is reached. A good deal of criticism was directed to the penalties proposed to be inflicted by Clause 14 for overlaying infants. The maximum penalty proposed was a fine of £10 which might be increased to £25 if the person who caused the death was under the influence of drink at the time, and the punishment might be supplemented by a term of imprisonment not exceeding three months. Several members of the committee expressed the view that the provisions of the clause were too drastic, that it would cause injustice and bring hardship to the poorest mothers in the country, and that negligence ought to be proved before a person was convicted. Mr. MACLEAN, in supporting the clause, however, pointed out that 1400 or 1500 children lost their lives every year through being overlaid, and in 85 per cent. of the cases the mothers were censured by the coroner's jury for neglect. Ultimately Mr. SAMUEL promised to bring up a redrafted clause at a later stage which he hoped would meet the approval of the committee. In the meantime Clause 14 was deleted from the Bill.

The Budget.

The features of the Budget, which was presented to the House of Commons on Thursday, May 7th, are the inception of a scheme of old age pensions and a reduction of the sugar duty. The age at which the pensions are to commence has been selected at 70 years and the amount of the pension is fixed at 5*s.* per week, with the limitation that only persons with an income of less than 10*s.* a week are to be eligible. There is no alteration in the income tax but the differentiation in favour of earned incomes is maintained.

Infant Life Protection (No. 2) Bill.

Lord ROBERT CECIL has introduced into the House of Commons a Bill "to prevent the destruction of children during birth." It is entitled the Infant Life Protection (No. 2) Bill and has been read a first time. He has the support of Mr. SHACKLETON, Mr. CHIOZZA MONEY, and Mr. SIMON in presenting the measure.

The Poisons and Pharmacy Bill.

The Joint Committee of both Houses of Parliament on the Poisons and Pharmacy Bill heard evidence on Tuesday. Mr. J. R. YOUNG, Warrington, President of the Pharmaceutical Society of Great Britain, and Mr. J. RUTHERFORD HILL, Secretary, Pharmaceutical Society, Edinburgh, both expressed themselves hostile to permitting limited liability companies using the name of chemists and druggists. Mr. HILL quoted extracts from a letter which he had received from Professor HARVEY LITTLEJOHN of the University of Edinburgh on this subject. "It has been the immemorial custom in Scotland," wrote Professor LITTLEJOHN, "in contradistinction to the general practice in England, for doctors not to dispense their own medicines but to have their prescriptions made up by 'chemists' or 'chemists and druggists' as they are called. The term chemist and druggist has always had the meaning *qualified* chemist, and such confidence does the medical profession of Scotland show in this title that it is a *common* occurrence to hear the doctor remark when asked by the patient where he ought to get the prescription made up 'Oh, any chemist or druggist.' The title as used in Scotland carries with it a guarantee of professional standing which has in later years been somewhat depreciated by the numerous drug stores which have arisen. The medical profession demand a guarantee of accuracy in dispensing, and this can only be obtained by properly qualified dispensers being employed in the making up of all prescriptions, whether these contain poisons or not."

HOUSE OF COMMONS.

WEDNESDAY, MAY 6TH.

Hospital Accommodation at Tidworth Barracks.

Captain FABER asked the Secretary of State for War whether the hospital accommodation for Tidworth Barracks was now definitely completed.—Mr. HALDANE answered: The reply is in the negative.

Captain FABER further asked whether the right honourable gentleman would state the material of which the isolation hospital at Bulford was built, seeing that in reply to a question asked in the House on April 30th he said that the scarlet fever cases were in the isolation hospital at that place.—Mr. HALDANE replied: The isolation hospital is built of corrugated iron lined with matchboarding.

Diphtheria and Wood Pigeons.

Major ANSTRUTHER-GRAY asked the President of the Local Government Board whether his attention had been called to the prevalence of a disease, diagnosed as akin to diphtheria, in wood pigeons, cats, and other birds and animals; whether, in view of the large quantities of diseased wood pigeons discovered in several counties during the last winter he would cause a full and searching inquiry to be made as to whether this disease was dangerous to man, and if so, what steps should be taken to cope with it.—Mr. BURNS furnished the following written answer: My attention has been called to the existence of this disease, and I have already caused a pigeon suffering from it to be examined at the Lister Institute. It was found that the disease in it was not due to the same organism or microbe as that causing human diphtheria, nor to the organism which caused a rather similar outbreak in pigeons in 1907, which was investigated by the Local Government Board at the time. The nature of the organism causing the recent outbreak is still being investigated, but there is some difficulty in continuing the investigation, as the disease has apparently now died out. I am advised that, so far as can be gathered, there is no evidence that the disease is dangerous to man.

THURSDAY, MAY 7TH.

The Sanitary Condition of Factories.

Mr. CHIOZZA MONEY asked the Secretary of State for the Home Department whether his attention had been directed to a report on the cutlery trade of Solingen by Dr. Harold Scurfield, the medical officer of Sheffield, according to which one of the most noteworthy features among the German factories was that it was compulsory for the owners to provide lavatory basins with hot and cold water, shower baths, and clothes' lockers for the use of the employees, with the result that the men went home from their work in clean clothes and with clean hands and faces, whereas at one time the Solingen workmen worked under the filthy conditions which frequently obtained at Sheffield; and whether he could promise legislation to increase health and industrial efficiency through the compulsory provision of the means of cleanliness for British workpeople.—Mr. GLADSTONE replied: Yes, sir, the attention of the Home Office has been called to this report and I may say that the conditions of work at Solingen had already been the subject of inquiry by the Home Office in connexion with the framing of regulations for the grinding industry. The feature mentioned by my honourable friend as well as other and more important features in the German factories are receiving our attention. The provision of washing and cloak-room accommodation has hitherto only been required by law in factories and workshops in this country where danger to health exists, as, for example, from the use of poisonous materials. The point is always borne in mind in framing regulations for dangerous trades, and requirements on the subject have been included in a number of the existing codes. I am not prepared, however, to promise legislation to make such provision generally compulsory in all factories and workshops.

Vaccine Lymph.

Mr. LUPTON asked the President of the Local Government Board whether he was aware that on March 9th, 1908, Doris Irene Leese, daughter of George Leese, of 8, Grove-road, Fenton, Staffordshire, died at the age of three months as the result of vaccination, as shown in the death certificate; and if in consequence he would take steps to stop the distribution by the Local Government Board of vaccine lymph until some stuff had been discovered which could be used without danger.—Mr. BURNS answered: My attention has been called to this case and I am making inquiry with regard to it. I could not, however, undertake to stop the issue of glycerinated calf lymph.

The Colonial Surgeon of St. Helena.

Major ANSTRUTHER-GRAY asked the Under Secretary of State for the Colonies whether, in view of the position which had lately arisen, and might arise again, owing to the only medical man in St. Helena being incapacitated from work, and the distance and delay involved in procuring other medical assistance, he would consider the desirability of appointing an assistant medical officer for that colony.—Colonel SEELY said in reply: The Secretary of State has not received any intimation of the colonial surgeon of St. Helena being incapacitated from work and regrets that he cannot add anything to the answer returned by my predecessor to the question asked by the honourable and gallant Member on the same subject on March 26th last.

Boric Acid as a Preservative.

Mr. STUART SAMUEL asked the President of the Local Government Board whether he was taking any steps by Order in Council under the Public Health (Regulation of Foods) Act, 1907, for the regulation of the proportion of boric acid that might be employed in articles of food, and if so whether he could give some definite statement on the subject at an early date in order to allay confusion in the public mind and to assist the local authorities in deciding what line of action they should take in the matter.—Mr. BURNS furnished the following written answer: I am giving attention to this matter and have directed inquiries to be made with regard to the present position of preservatives in certain food-stuffs. The matter is one which requires careful investigation and I am not at present in a position to make any definite statement with respect to it.

MONDAY, MAY 11TH.

The Bulford Isolation Hospital.

Captain FABER asked the Secretary of State for War what was the accommodation in the Bulford Isolation Hospital for scarlet fever cases, when this isolation hospital was erected, and how long it had been used for that purpose; and what was the total number of regiments and batteries within a six-mile radius of Bulford.—Mr. HALDANE replied: The hospital has accommodation for four beds; it was completed in January, 1904, and has been used as an isolation hospital since that date. The accommodation has been supplemented by a hospital marquee erected in the infectious inclosure on April 23rd, 1908, but this has not yet been required. The number of batteries and regiments within a radius of six miles is 18.

The Temperature of Factories.

Mr. Devlin asked the Secretary of State for the Home Department whether his attention had been called to a case heard at the Derry city petty sessions on April 30th last in which Messrs. Tillie and Henderson, Foyle Factory, were summoned by Miss Hilda Martindale, inspector of factories, for having failed to take adequate measures for securing and maintaining a reasonable temperature in a room in the factory so as not to interfere with the purity of the air; whether he was aware that it was given in evidence that in one of the rooms where 86 women and girls were working the temperature was found to be 46° in one part and 49° in another, that the room was not provided with any means of securing warmth and the 26 windows in it were closed owing to the cold, that it was contended by the defence that the breath of the workers was sufficient to heat the rooms properly, that medical evidence given was to the effect that a temperature of 46° to 49° induced lung trouble, neuralgia, and rheumatism, and that the warmth produced by the breath of the workers vitiated the air; was he aware that it was contended by the defence that the temperature of prisons was good enough for the workers, and that the bench by a majority dismissed the case, and refused to state a case except on a point of law; and whether, in view of the importance to the workers of the issue raised in this case, he proposed to take any further action with regard to it.—Mr. Gladstone answered: I have received a report of the proceedings in this case and the facts are substantially as stated in the question. I cannot agree with the view taken by the court that a temperature of 46° was a reasonable temperature for persons engaged in a sedentary occupation, and it is a view, I think, which few, if any, other courts would take. No other case of the kind has come to my notice. I am advised that there is no appeal from the decision, but the matter shall have my consideration with a view to seeing what further steps may be desirable.

Irish Universities Bill.

Mr. J. H. M. Campbell (speaking on the motion for the second reading of the Irish Universities Bill) said in the course of his speech that the Bill seemed to perpetrate a great injustice upon the Royal College of Surgeons in Ireland. He was, however, convinced that when this case was presented to the Chief Secretary he would realise the injustice which the Bill would inflict upon that old institution. There were three schools of medicine in the city of Dublin. One of them was in Trinity College, University of Dublin. It was not available for students whose means did not enable them to pay the high fees or for those who wanted to get their medical degree in as short a period as possible. There was also the St Cecilia-street School of Medicine, which had been the medical faculty of the Catholic College, and it of course would become the medical school of the new University. Not only did the Roman Catholic bishops encourage it in every way in their power, but it was now notorious that in the South and West of Ireland no medical applicant for any post had a chance with the local bodies unless he could show the diploma of the St. Cecilia street School. Therefore that school had a tremendous advantage over the Medical School of the Royal College of Surgeons in Ireland, which had been in existence since 1734. The Medical School of the Royal College had been most successful, although it had no endowment from the State. It had lived on its own merits. It had neither politics nor particular views and it had been a conspicuous success. It had over 3000 Licentiates. What was going to be its position under the Bill? The new University created by the Bill would at once adopt the St. Cecilia-street School as its school of medicine. It would have all the special equipment of bursaries, grants, and professorships. How would it be possible for the School of Medicine attached to the Royal College of Surgeons to compete with it? The School of the Royal College would inevitably go under and they would thus have killed the only undenominational school of medicine in Ireland. How could the Government resist the demand of the Royal College for some compensation, so that they might be able to compete, even at a distance, with the St. Cecilia-street School? That demand was consistent with ordinary justice.

Mr. Birrell (the Chief Secretary to the Lord Lieutenant), in replying to the debate, made no reference to the case of the Medical School of the Royal College of Surgeons.

The motion for the second reading of the Bill was carried by 344 votes to 31.

TUESDAY, MAY 12TH.

The Disposal of Trade Effluents.

Answering Mr. Clough, Mr. Burns said: I am desirous of introducing legislation to deal with the subject of trade effluents, if possible, this session, but I cannot state beforehand what will be the contents of the measure.

Female Inebriates in London.

Mr. Bright asked the Secretary of State for the Home Department whether he was aware that, at the County of London sessions, the magistrates had recently been compelled to discharge several female habitual drunkards who would have been committed to homes had there been any accommodation to receive them; whether this situation had arisen through the failure of the County Council to provide such accommodation; and whether he proposed to take any, and, if any, what, action in the matter.—Mr. Gladstone replied: I am sorry to say that magistrates in London have recently had many such cases before them. In answer to a question put to me in February I set out at some length the causes which have given rise to this situation. I have appointed a committee, of which the honourable Baronet the Member for the Chippenham division is chairman, "to inquire into the operation of the law relating to inebriates and to their detention in reformatories and retreats, and to report what amendments in the law and in its administration are desirable," and I hope the committee will be able at an early date to suggest a solution of the difficulties which are rendering the Inebriates Act of 1898 practically inoperative so far as London women are concerned.

Belfast Health Commission.

Mr. Devlin asked the Chief Secretary to the Lord Lieutenant of Ireland whether he could state the probable cost of the Belfast Health Commission; and whether the whole of the cost would have to be defrayed by the ratepayers.—Mr. Birrell answered: The cost of the inquiry in question has not yet been ascertained. It has been arranged that £500 of the cost will be borne by the Exchequer. The remainder will fall upon local rates.

The Housing, Town Planning, &c., Bill.

Mr. Burns, in moving the second reading of the Housing, Town Planning, &c., Bill, drew attention to the bearing of overcrowding and defective housing on disease. Bad as overcrowding was in the towns, it was in some respects relatively as bad in the country. In rural districts the tendency was to get worse and worse. One could give individual instances where families were crowded in small cottages, bad in structure and insanitary in condition, and where the conditions, if they happened to be in a Liverpool, Glasgow, or London slum would be termed intolerable. He pointed out the fact that in the whole of England 4 per cent. of the population lived in one room, in London 14 per cent., in Edinburgh 17, in Glasgow 26, in Dublin 36, in Paris 26, and in Berlin 50 per cent. How did this reflect upon the health of the population? In Berlin they would find that the death-rate ranged from 18 to 20, and in London from 14 to 16. They would further find that in London, in diseases like scarlet fever, typhus fever, and even tuberculosis, they compared well with towns abroad, where the overcrowding was greater. The Government, therefore, promoted the Bill not only for the convenience of the people of the country but in consideration of their health. He went on to say that back-to-back houses gave a very high death rate, and in stable dwellings—which he trusted they would get rid of quicker than some people thought—the proportion of deaths to the rest of the community was still higher. In London wherever they had great density per room they found infant mortality and overcrowding producing disease to an extent which they had no right to permit. The Government hoped to modify and ultimately to abolish these bad conditions of housing. The right honourable gentleman then went on to detail the machinery of the Bill.

In the course of the subsequent discussion Mr. Adkins and several other members spoke favourably of the proposals in the Bill relating to the appointment of medical officers of health.

The Bill was ultimately read a second time.

BOOKS, ETC., RECEIVED.

American Climatological Association. (Secretary and Treasurer: Guy Hinsdale, M.D., Hot Springs, Va., U.S.A.)

Transactions of the American Climatological Association. For the Year 1907. Volume XXIII. Price not stated.

RUSSELL.—On May 10th, at Guildford, after a short illness, Francis Rutherfurd Russell, M.D., aged 55 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

JUSTICES AND THE ADULTERATION OF MILK.

THERE is not much encouragement to those intrusted with the carrying out of the provisions of the Sale of Food and Drugs Act to find that on the slightest technical ground cases of adulteration taken before the magistrates are dismissed, or, if not thrown out, are met with fines totally inadequate to the seriousness of the offence. Attention was called in THE LANCET at the end of last year (Dec. 7th, 1907, p. 1632) to the threat of the Sale of Foods and Drugs Act committee of the West Sussex County Council to withdraw from its labours unless it was supported by the infliction of adequate penalties by the justices in cases of adulteration. But the publicity which was given to the matter at the time does not appear to have had much effect upon the justices, inasmuch as the committee in its next report, which was submitted to the county council at its meeting at Horsham on May 8th, remarked: "The committee again desired to draw to the attention of the county council that the success of their labours depended very largely upon the infliction of adequate penalties by the justices of the county in cases of conviction of adulteration under the Sale of Foods and Drugs Act." The penalties inflicted for adulterated cocoa were those complained of six months ago, but in the present report the article of diet was milk of which the county analyst, Dr. Otto Hehner, had reported "a very high percentage of adulteration, no less than 25·5 per cent. of the milk samples analysed being adulterated." During the past quarter 34 samples of milk were submitted for analysis, and out of that number 11 were declared to be adulterated. There were prosecutions in seven cases, and of these seven two were dismissed on technical grounds, two were dismissed because the adulteration, in the opinion of the justices, was so small (9 and 13 per cent. respectively of added water), in one case there was a penalty of £5 and costs, and in another case a penalty of £2 2s. and costs. These penalties were no deterrent because three weeks later the same defendants were summoned again for selling adulterated milk, and while Mr. Wilberforce, the chairman of the committee, did not state what happened in these cases he complained bitterly that the same notice of prosecutions of that kind was not taken as in other places. He was probably referring to the recent fines in other parts of the country of £50, £100, and even imprisonment. Although himself a magistrate for West Sussex, Mr. Wilberforce spoke very strongly upon the matter and appealed for adequate and efficient penalties. Naturally, owing to the fact that the majority of the members of the county council are magistrates there was some objection to Mr. Wilberforce's caustic criticism, it being held that the magistrates, like judges, must not be attacked upon their decisions. But the fact cannot be disputed that to adulterate milk is a fraud upon the public and should be adjudicated upon by the justices as a case of fraud, irrespectively of who the defendant may be. Many cases before West Sussex justices could be cited showing the imposition of far more rigorous penalties inflicted for offences much less serious than the adulteration of foodstuffs. The justices should look upon these cases as charges of obtaining money by false pretences, which is, if not in the eyes of the law, the same thing as selling milk and water as milk. There seems to be very good ground, as was hinted at during the council meeting, for petitioning the Lord Chancellor to put justices on the benches who will see that the law is properly administered, particularly so when the chief constable passes over cases of adulteration, "knowing pretty well what the tone of our benches is" (the words in inverted commas are those actually used by Mr. Wilberforce), and that it was hopeless to institute a prosecution.

STRANGE DEATH OF AN EPILEPTIC.

AN inquest was held at Whipsnade on April 11th by the deputy-coroner for Bedfordshire to inquire into the circumstances of the death of a Dunstable publican, aged 41 years, whose body was found lying in a field near Whipsnade in a completely nude state on the morning of April 10th. It appeared from the evidence that for some years the deceased had been subject to "fits" and that on one occasion he had "strayed away and did not come home until three o'clock in the morning." The death of his wife last September greatly disturbed him and to the knowledge of one of the witnesses, a man named Green, who was his sole assistant, he had since then had four fits which set in suddenly causing him to "fall down like a stone." Green said that he did not cry out on these occasions but that once on recovering from a fit he complained of a sore tongue. The deceased never drank to excess either before or after the death of his wife. On April 7th he had a fit in the morning. Green saw him in it; he was lying in bed with blood coming from his mouth. On the 9th he ate a hearty dinner at noon. After dinner Green went to some races, returning at about 7 P.M., when he found that the cellar work had been done during his absence and that the deceased was not at home. A letter addressed to his brother in London was lying on the table in the parlour, and during the afternoon he had sent one of his children with a telegram which was also intended for his brother. Another witness named Mead said that on the 9th at about 6.45 P.M. the deceased asked him to mind the place as he had to go out on business of importance. He then left, taking a footpath which led to the Downs. A farmer living at Whipsnade said that about 8 A.M. on the 10th he found the naked body of a man in a field where there was no footpath and the clothing was lying scattered about not far off. He at once informed a police-constable who stated in evidence that he saw the body of the deceased in the field; it was naked and quite cold and stiff, lying in the prone position with the head resting on the right arm. About three yards from the body there was a quantity of clothing and some 150 yards distant near a hedge he found two socks and a boot. A medical man who attended the inquest said that he had examined the body which was then lying as described by the constable. The teeth were clenched on the tongue, which was bitten, and there were blood and froth on the tongue. There were no marks of violence except a slight abrasion on one elbow. The history of the case was one of epilepsy, going back for two years. Under the influence of these fits the man would be for the time insane and this would account for his stripping off his clothing. He attributed death to suffocation, owing to the deceased having fallen with his face resting on his arm, a view with which the jury unanimously concurred. The letter which the deceased left for his brother did not cast any light on the subsequent occurrences.

"REMARKABLE TESTIMONY."

WE extract from the advertisement columns of the *News of the World* of Sunday, May 10th, the following, which is described by our contemporary—with whom we agree—as remarkable testimony:—

> "Dr. Chas. Forshaw, M.D., Ph.D., F.R.M.S., F.C.S., D.Sc., the eminent scientist and litterateur, of Baltimore House, Bradford, Yorks, Editor of Yorkshire Notes and Queries, etc., makes the following laudatory remarks about the safety, purity, and efficacy of Dr. Cassell's Tablets.
>
> "Dr. Forshaw says:—'I have thoroughly tested, both scientifically and practically, the preparation known as Dr. Cassell's Tablets, and can conscientiously recommend it as an eminently safe and effective remedy for all forms of nerve and bodily weakness. My knowledge of Dr. Cassell's Tablets leads me to the opinion that the ingredients employed in their composition form a unique synthesis, the whole combining to form what I consider to be a remarkably potential medicine, quite safe for young and old, in cases of nervous prostration, debility, anæmia, loss of flesh, malnutrition, children's weakness, spinal and nerve paralysis, and many forms of stomach and kidney troubles. I read they can be taken by stout people as well as thin without fear of increase of adipose tissue, and from their composition I should consider this to be the case.
>
> "'I have never before testified to a patent medicine, but now take pleasure in the interest of science and humanity, in making the above statements.'
>
> "Dr. Cassell's Tablets can be obtained for 10½d., 1/1½ and 2/9 (containing nearly four times the 10½d. size), of all chemists. Advt."

Mr. Forshaw is a dentist who lives, according to the Dentists Register, at Hustler Terrace, Bradford, and his wealth of American degrees has received some comment in THE LANCET. Having been in dental practice before July 22nd, 1878, his name is included in the Dentists Register, but if he is going to recommend in the lay press an "effective remedy for all forms of nerve and bodily weakness" the General Medical Council may consider his inclusion among official dental practitioners.

THE INTERMEDIATE EXAMINATION FOR THE DEGREE OF M.B. LOND.

To the Editor of THE LANCET.

SIR,—Anyone comparing the time, work, and knowledge required to pass the Intermediate M.B. Lond. (especially in honours) with the same for an ordinary pass B.Sc. must acknowledge that those who have obtained the former are as fairly entitled to a graduation in science as are the latter. I would therefore urge through you the claims of those who pass the Int. M.B. Lond. with honours to the B.Sc. degree, especially seeing that that degree can now be obtained for one branch of science, such as engineering or chemistry, &c. It would considerably enhance (and legitimately so considering the extra exertions required) the value of the M.B. degree itself and would be a consolation, as well as advantageous in after life, to those who like myself have from family or other reasons prevailing at the time been prevented from proceeding to the final M.B. After devoting such time and energy it is disappointing to have nothing to show for them, especially when, as in my case, not even the Medical Directory, in spite of repeated intimations, will insert the fact.

I am, Sir, yours faithfully,
INT. M.B. LOND. (HONOURS).

SPIGELIA: A CASE OF MISTAKEN IDENTITY.

ONE of the most remarkable instances of the substitution of a drug by others is afforded by spigelia or pink-root which formerly was esteemed as an anthelmintic. In Bulletin No. 100 of the United States Bureau of Plant Industry Mr. W. W. Stockberger shows that for many years almost the whole of the so-called pink-root that has been employed in medicine has been derived from entirely different plants of doubtful efficacy which have masqueraded as pink-root. True pink-root is the product of Spigelia marilandica and Spigelia anthelmia, plants which were largely used by the native inhabitants of the southern United States and later by the British colonists who introduced them into Europe, where they were cultivated. As pink-root gained a wider reputation as an anthelmintic other plants were substituted for it, particularly a species of ruellia, with the result that unfavourable accounts of its action brought the drug into disrepute. This substitution became more prevalent when the Civil War cut off all southern supplies of the true drug. In its place the collectors usually supplied the roots of a species of ruellia. As time went on various adulterants of pink-root came to be regarded as genuine, so much so, indeed, that they have been described as such by various writers of text-books on materia medica. The fact that ruellia has so largely supplanted the true drug as to be studied pharmacologically and described in medical and botanical works shows that in the majority of cases in which the adulterant was present it was not detected. *Fortunately, ruellia does not appear to* possess a marked physiological action.

COMPOUND LIQUORICE POWDER.

THE compound liquorice powder of the Pharmacopœia is objected to by some medical men in the case of persons affected with diabetes, obesity, gout, and some other diseases. Two-thirds of the powder consists of the sweet substances, sugar and liquorice, of which the former unduly increases the bulk of the preparation without materially increasing its therapeutic efficiency. Attempts have been made to improve the powder by omitting the sugar, thus reducing the dose by one-half, but the product is not readily miscible with water. In the *Pharmaceutical Journal* of March 28th the late Dr. A. J. Balmanno Squire suggested the replacement of both sugar and liquorice by powdered sweet almonds and gum acacia. The suggested preparation contains senna, two parts; fennel and sulphur, of each one part; and eight parts of a powder containing almonds and gum acacia in the proportion of eight parts to one. The omission of liquorice is unfortunate since the preparation is named after that ingredient. It would seem to be more reasonable to retain the liquorice, which at the most does not contain more than 7·5 per cent. of the sweet principle glycyrrhizin, and to add a suitable mixture of gum and saccharin to render the powder miscible with water and to impart a sweet taste. Such a product would gain in palatability by reason of its smaller dose.

◆

Medical Referee.—We do not approve of the departure of the insurance company, though we do not think that undertaking the work would consequently become exactly unethical.

F. E. H.—Assuming the facts to be as stated, our correspondent has been treated in an unneighbourly manner. We doubt, however, whether the General Medical Council would consider such conduct censurable.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—A. Whitfield, E. G. Graham Little): at 5 P.M.

Cases:

Dr. Radcliffe-Crocker: (1) Mycosis Fungoides (private); (2) Case for Diagnosis (private).

Dr. Adamson: (1) Nodular "Ringed Eruption" (Granuloma Annulare); (2) Small Follicular Syphilide.

Dr. Whitfield: A Case of Disseminated Lupus with Chronic Lymphangitis of the Face and Osteo-arthritis.

Dr. Sequeira: Two Cases of Sclerodermia.

Dr. Parkes Weber: ? Multiple Xanthoma of the Face of the Diabetic Type in an Infant.

Dr. Graham Little: (1) Varus Nodulosis (Brooke); (2) Pseudo-pelade (Brocq); (3) Pseudo-xanthoma Elasticum.

FRIDAY.

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan): at 8 30 P.M.

Paper:

Sir Frederick Treves, Bart., G.C.V.O.: Preventive Medicine in Panama.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretary—Reginald Morton): at 8.30 P.M.
(In the Rooms of the Royal Philosophical Society, 207, Bath-street, *Glasgow.*)

Papers:

Dr. H. Lewis Jones: Instantaneous X Ray Photography.

Dr. Dawson Turner: "Some Reflections based upon the Work done in the Electrical Department of the *Royal Infirmary,* Edinburgh.

Dr. Samuel Sloan: Ionic Medication in the Treatment of Some Obstinate Cases of Pelvic Disease in Women.

Exhibition of Electrical Apparatus (in the same place from 3 P.M. till 10.30 P.M.).

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Conversazione. Presentation of the Fothergillian Medal to Sir A. E. Wright, M.D. Annual Oration:—Mr. C. Dent: The After-results of Injuries.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—5 P.M., Wightman Lecture:—Mr. W. Cheyne: On the Defensive Arrangements of the Body as Illustrated by the Incidence of Disease in Children and Adults.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY, Harrogate.

SATURDAY.—Meeting.

MEDICO-LEGAL SOCIETY, 22, Albemarle-street, W.

TUESDAY.—8.15 P.M., Narration of Cases and Exhibits of Medico-Legal Interest. Mr. J. H. Evans: The Medico-Legal Significance of Gonorrhœa.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. Galloway: Clinique (Skin). 5.15 P.M., Lecture: Dr. B. Abrahams: Modern Views on Rheumatoid Arthritis (with lantern slides).

TUESDAY.—4 P.M., Dr. C. O. Hawthorne: Clinique (Medical). 5.15 P.M., Lecture:—Mr. F. C. Wallis: Fistula in Ano.

WEDNESDAY.—4 P.M., Mr. P. J. Freyer: Clinique (Surgical). 5.15 P.M., Lecture: Mr. A. H. Tubby: Surgical Diseases of Children.

THURSDAY.—4 P.M., Mr. Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. T. G. Stewart: Syphilitic Affections of the Spinal Cord.

FRIDAY.—4 P.M., Dr. StClair Thomson: Clinique (Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, road, W.

MONDAY.—12 noon, Lecture:—Dr. Low: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—*Dr. Robinson: Gynæcology.*

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. 2.15 P.M., Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Low: Insects as Carriers of Disease.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. 12 15 P.M.: Lecture:—Dr. Pritchard: *Practical Medicine.* 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eyes. 2.30 P.M., Operations. Dr. Robinson: Diseases *of Women. 5 P.M., Lecture:*—Dr. Beddard: Medicine.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Baldwin: *Practical Surgery.*

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. 2.15., P M., Dr. Davis: *Diseases of the Throat, Nose, and Ear.* 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. K. Scott: Emergency Operations in Eye Affections.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children, 2 P.M., Medical and Surgical Clinics X Rays. Dr. Scott: Diseases of the Eyes. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. J. H. Evans). 2.30 P.M., Medical Out-patient (Dr. Whipham); Nose, Throat, and Ear (Mr. Carson); X Rays. 4.30 P.M., Medical In-patient Clinic (Dr. Whiting).

TUESDAY.—Clinic:—10 A.M., Medical Out-patient (Dr. Auld). 2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Surgical (Mr. Edmunds); Gynæcological (Dr. Giles). 4.30 P.M., Special Demonstration of Selected Medical Cases (Dr. R. M. Leslie).

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (*Dr. Whipham*); Skin (Dr. Meachen); Eye (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations. (*Dr. Giles*). Clinics:—Medical Out-patient (Dr. Whiting); Surgical (Mr. Carson); X Rays. 3 P.M., Medical In-patient (Dr. Chappel). 4.30 P.M., Throat Operations (Mr. Carson).

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. J. H. Evans). 2.30 P.M., Surgical Operations (Mr. Edmunds). *Clinics:*—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie). 4.30 P.M., Special Demonstration of Selected Eye Cases (Mr. Brooks).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2.15 P.M., Sir Dyce Duckworth: Medicine. 2.30 P.M., Operations. 3.15 P.M., Mr. W. Turner: Surgery. 4 P.M., Mr. L. A. Lawrence: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2.15 P.M., Dr. R. T. Hewlett: Medicine. 2.30 P.M., Operations. 3.15 P.M., Mr. Carless: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2.15 P.M., Dr. F. Taylor: Medicine. 2.30 P.M., Operations. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical, 11 A.M., Eye. 2.15 P.M., Special Lecture:—Dr. F. Taylor: Emphysema of the Lungs.

THURSDAY.—2.15 P.M., Dr. G. Rankin: Medicine. 2.30 P.M., Operations. 3.15 P.M., Sir W. Bennett: *Surgery.* 4 P.M., Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2.15 P.M., Dr. R. Bradford: Medicine. 2.30 P.M., Operations. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 3.15 P.M., Special Lecture:—Mr. McGavin: Acute Inflammation in Long Bones.

SATURDAY.—2.30 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Lecture :—Mr. Sargent: Cerebral Abscess.

FRIDAY.—3.30 P.M., Lecture :—Dr. J. Taylor: Sclerotic Diseases of Cord.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, 7, Fitzroy-square, W.

THURSDAY.—5 P.M., Lecture :—Sir William Allchin: Some Interrelations of Thoracic and Abdominal Disease.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture :—Dr. Poynton: Pyo-pericarditis.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), West London (2.30 P.M.).

TUESDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (20th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.).

THURSDAY (21st).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.).

FRIDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (23rd).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) *do not* reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

The Ingleby Lectures

ON

DANGERS AND TREATMENT OF MYOMA OF THE UTERUS.

at the University of Birmingham on May 7th and 14th, 1908,

ISTOPHER MARTIN, M.B., C.M.
EDIN., F.R.C.S. ENG.,
SUR IRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.

LECTURE I.

Delivered on May 7th.

GENT , —It is admitted on all hands that myoma or fibroid t mour of the uterus is a common condition. I do not know what percentage of women suffer from them; but in a considerable proportion of those who consult a gynæcologist myomata are present and causing trouble. The more I see of the disease, the more I follow up the cases, the more impressed am I by the risks of the condition and the frequency with which grave complications arise. To-day I propose to call your attention to certain of these dangers and in my second lecture to discuss the methods of treatment.

HÆMORRHAGE.

Hæmorrhage from the uterus is the commonest symptom of myoma and is present in the great majority of instances. It varies much in different cases. In some, with even a large fibroid, it is only a rather profuse or prolonged menstruation. In others, with perhaps quite a small growth, there are terrific floodings. The nearer the tumour to the cavity of the uterus the more severe the flooding. Thus in the subserous growths it is slight, in the interstitial it is profuse, and in the submucous and polypi it is excessive. In some cases there is a constant dribbling of blood-stained watery fluid, with monthly exacerbations. In others there are sudden and alarming floodings, with intervals of weeks or months with little or no loss.

Some years ago I was consulted by a woman, aged about 45 years. She had had several severe hæmorrhages, with clear intervals of six or eight weeks. I found that she had a submucous fibroid, about as big as a lemon, just beginning to dilate the cervix. I advised her to have it removed but she shrank from an operation. She consulted a physician who put her on tonics and ordered her to Blackpool. The evening before she was to go away, whilst dining at a friend's house, she began to flood tremendously. She was removed home on an improvised stretcher and when I saw her, about an hour later, she was nearly pulseless. I plugged the vagina with iodoform gauze, renewing it every 48 hours. Each time when I changed the plug the bleeding started afresh. In about ten days she had rallied somewhat and I ventured to remove the growth by enucleation per vaginam. The patient made a good recovery and had no further trouble.

In 1899 a woman suffering from myoma was sent to the Birmingham and Midland Hospital for Women. She had a long history of floodings and when admitted was blanched to the last degree. She was restless, vomiting, and extremely weak. She had a temperature of 100° F. and a rapid, thready, irregular pulse. On examination a large submucous myoma was found. Whilst in hospital no further hæmorrhage occurred; but no operation was attempted, as the patient was too ill. She never rallied from the state of collapse and died about 48 hours after admission, as the direct result of the repeated losses.

It is rare for a patient to actually bleed to death from a myoma. She usually develops a condition of marked chronic anæmia. She has dilated pupils, œdema of the face and feet, loud hæmic murmurs, palpitation, breathlessness, and faintness on the slightest exertion. One of my patients who was admitted in this condition got out of bed to go to the lavatory and fell in a "dead faint" on the floor. She was so weak that I had to keep her in hospital and nurse her up for weeks before I ventured to operate. This chronic anæmia is the chief cause of the brown atrophy and fatty degeneration of the heart muscle which occurs in many cases of neglected fibroid. It is also the main factor in producing thrombosis and phlebitis of the veins of the pelvis and lower limbs, and secondary embolism of the pulmonary artery. These lesions are to blame for some of the deaths after operation; and I think that the responsibility for such deaths rests more with those who have delayed the operation than with the surgeon who performs it.

PAIN AND DISCOMFORT.

Uncomplicated myomata do not as a rule give rise to much pain; certainly there is nothing approaching the agonies of cancer. Most patients complain rather of discomfort and uneasiness. The menstrual periods are sometimes painful, from spasmodic contractions of the uterus endeavouring to expel a submucous tumour. On the other hand, subserous fibroids may attain a great size, and only give rise to inconvenience from their weight and pressure on neighbouring parts. But complicating myoma, there are often other lesions of the pelvic organs, such as adherent and inflamed ovaries and tubes, and then there is severe pain.

PRESSURE SYMPTOMS.

The pressure symptoms of myomata are numerous and frequently call for surgical treatment. Pressure on the rectum causes constipation and hæmorrhoids. Pressure on the iliac veins causes varicose veins of the legs and vulva. Pressure on the sacral plexus of nerves causes neuralgic pains, sciatica, and cramps, though seldom paralysis. Pressure on the uterus may cause backward displacement or even total prolapse of the organ. By far the most serious and distressing group of symptoms are those due to pressure on the urinary organs. Pressure on the urethra or neck of the bladder causes retention of urine. In some cases the first indication of the presence of a myoma is sudden retention of urine, necessitating the passage of a catheter. It usually occurs in young unmarried women. It is generally due to a fibroid in the posterior wall of the uterus, retroverting the uterus and tilting the cervix forwards against the pubes. In fact, these cases remind one very much of the cases of retention due to retroversion of the gravid uterus. In some cases there is a gradually increasing difficulty in passing urine, the patient having to strain and probably never really emptying her bladder. This is a frequent occurrence where the fibroid is impacted in the pelvis and unable to rise into the abdomen. In other instances we find the bladder raised quite out of the pelvis and spread out as a thin flattened bag (like a rubber hot-water bottle) between the abdominal wall and the tumour. In operating on such cases the surgeon in opening the abdomen may easily cut into the bladder. I did so in one case, a patient of Mr. M. Hallwright, the bladder reaching up to the umbilicus, uncovered in front with peritoneum. I sewed up the wound in the bladder, opened the peritoneum higher up, and performed hysterectomy. The patient got well without any bladder trouble, but at the time the accident caused me much anxiety.

In another group of cases the patient is unable to hold her urine for any length of time. Here the tumour presses on the bladder from above so that there is practically no room for it to expand. These patients have to rise in the night, perhaps every hour, to pass urine and they become worn out from want of sleep.

Cystitis seldom occurs as a result of myoma except by infection through a dirty catheter. Should it develop it is a serious complication, as the inflammation may pass up the ureter and cause pyelitis and pyonephrosis. I can recall two deaths caused in this way. If a woman has retention of urine from an impacted fibroid the strictest antiseptic precautions must be observed in drawing off her urine.

Pressure on the ureters is most apt to occur in cases where the tumour is developing in the broad ligament or growing from the cervix. In some instances the ureters are raised up out of the pelvis by the growth burrowing beneath them. In one case, in which I assisted one of my colleagues to perform hysterectomy, he found both ureters lifted up by the tumour and arching over it to reach the bladder, like a pair of braces over one's shoulders. In all such cases there is a great risk of the back pressure on the kidneys causing hydronephrosis, destruction of the renal substance, and death from uræmia.

LESIONS OF THE OVARIES AND TUBES.

Disease of the uterine appendages frequently complicates myoma. In some cases the surgeon opens the abdomen to remove a myoma and finds unexpected lesions in the ovaries and tubes which the tumour had masked, or he may operate for disease of the appendages and find in addition a small fibroid of the uterus. There are, of course, many cases where before operation both conditions were recognised as present and calling for treatment. The tubal lesions include salpingitis, hydrosalpinx, hæmatosalpinx, and pyosalpinx; the ovarian comprise ovarian cysts large and small, ovarian abscess, and chronic ovaritis. With any of these there may be dense pelvic adhesions matting together uterus, appendages, bowel, and omentum. These complications, especially that of pyosalpinx, add much to the difficulties and dangers of the operation. They are risks, however, that we cannot shirk, as the suffering of the patients without operation is often intense and the relief given complete.

The question arises, Is the myoma responsible in any way for the tubal or ovarian disease? I think, in many cases, it is. It is common knowledge that in most cases of myoma there is more or less endometritis. Further, the tumour may mechanically damage the tubes and ovaries by compression, torsion, and dragging, resulting in hydrosalpinx, hæmatosalpinx, &c. Septic changes may occur in the cavity of the uterus as the result of decomposition of clots or necrosis of submucous growths. Germs may then easily pass from the infected endometrium to the damaged tubes and ovaries, giving rise to salpingitis, pyosalpinx, and ovarian abscess. But I do not say that the myoma is the cause of the ovarian cysts so often found associated with it. We do not know the causes of these conditions. Probably neither the myoma causes the cyst nor the cyst the myoma; but both are due to some common fault in development, the nature of which is at present beyond our grasp. I see no evidence that diseased conditions of the ovaries and tubes can ever cause a myoma to develop in the uterus.

Lesions of the ovaries and tubes are found in about one-third of all cases of myoma submitted to operation. Noble in a study of 2274 cases found diseased conditions recorded in 37 per cent.; whilst they were present in 62 out of 218 cases he personally operated on. Dr. C. J. Cullingworth found them in 22 per cent. and Dr. Mary Scharlieb in 38 per cent. of their cases. In my own cases the proportion was not so high. I have now opened the abdomen 380 times for the treatment of myomata, and I found gross lesions of the uterine appendages in 53 of these (14 per cent.). There were ovarian tumours in 19, chronic or cystic ovaritis in 15, and salpingitis, hydrosalpinx or pyosalpinx in 19 cases.

HEART LESIONS.

It has been shown that myomata, especially those of large size and causing much hæmorrhage, exercise a very pernicious influence on the heart. The repeated hæmorrhages produce chronic anæmia; and, as a result, the heart is badly nourished. A large myoma causes mechanical obstruction to the circulation and increased peripheral resistance. The result is that the heart muscle undergoes fatty degeneration and brown atrophy. The latter condition was found by Fleck in seven out of 11 cases of myoma which died from heart failure. Dr. Thomas Wilson, the Ingleby lecturer of last year, has carefully studied the relation of myoma to heart disease, and says that over 40 per cent. of patients suffering from severe symptoms of myoma have some form of cardiac insufficiency. He urges the careful examination of the heart in all cases of myoma. He points out that ergot is contra-indicated if there be cardiac weakness, for it increases the peripheral resistance by contracting the arterioles. He advises the timely removal of the myoma, before the heart has deteriorated. Should heart disease have already developed the patient should be treated with rest and tonics before being submitted to operation. Finally, in those who recover from the operation a marked improvement takes place in the condition of the heart.

DEGENERATIVE CHANGES.

Myomata are peculiarly liable to various kinds of degeneration; indeed, I know of no other tumour so prone to secondary changes. They are found in about 20 per cent. of the cases. We may divide them conveniently into three great groups: (1) non-malignant degenerations *without* necrosis, occurring in about 14 per cent. of myomata; (2) non-malignant degeneration *with* necrosis, occurring in about 4 per cent. of myomata; and (3) malignant degenerations and complications, occurring in about 4 per cent. of myomata. Let us consider each group in turn.

1. *Non-malignant degenerations.*—This group is a large one and includes many different pathological processes. Amongst the mildest and most innocent are fatty degeneration, hyaline degeneration, and calcareous infiltration. These are found in tumours which have ceased active growth and may be looked upon as signs of their old age. They do not, as a rule, call for active interference. But there are other degenerations characterised by marked activity and rapid growth of the tumour. These include acute lymphatic œdema, myxomatous softening, cystic degeneration, angiomatous changes, adenomatous growths, and the curious condition known as red degeneration. There are certain clinical features common to nearly all these degenerations: (*a*) the tumour is usually, but not invariably, single; (*b*) after a period of quiescence it suddenly begins to grow rapidly, with increased pressure symptoms and often severe pain; (*c*) the tumour changes in consistence, become more elastic and softer; in the cystic variety it fluctuates and gives a thrill like an ovarian cyst; and (*d*) in many cases it becomes more vascular, the enlarged arteries being felt pulsating in its walls and a loud bruit being heard on auscultation. These changes may come on at any age but are most common about the menopause. They may even come on years after the cessation of menstruation. Amongst my 380 abdominal sections for myoma I found non-malignant degeneration recorded in 19 cases (5 per cent.), of which no less than 13 were examples of cystic degeneration.

Red degeneration.—Let me briefly call your attention to the curious condition known as red degeneration. It is sometimes called "hæmorrhagic degeneration." It is probably a form of acute aseptic necrosis and hence is termed by some writers "red necrobiosis." In Noble's collection of 2274 cases of myoma it is recorded 13 times, or 1 in 175. Whenever it does occur it causes serious symptoms and calls for immediate operation. Its essential cause is unknown. It is specially liable to occur in young pregnant women. The onset is sudden. There is acute pain with vomiting, a rapid increase in the size of the tumour, and often some degree of fever.

In a case on which I recently operated the symptoms were so sudden and severe that I thought the patient had a strangulated ovarian tumour. She was a young married woman who was about three months pregnant, and had no suspicion that she had a tumour of any kind. One evening she was seized with acute colicky pain in the pelvis, with vomiting and faintness. Her medical attendant, Dr. G. H. Mounsey, found her with some distension and a rapid pulse. She was obviously pregnant and to one side of the uterus was an elastic semi-cystic tumour. A few hours later she was worse and the tumour was distinctly larger. I was called in, diagnosed a strangulated ovarian tumour, and advised immediate operation. I opened her abdomen and found she was pregnant, whilst to one side of the uterus was a large myoma, undergoing red degeneration. I enucleated it without removing the pregnancy or the rest of the uterus. She aborted about 24 hours after the operation but otherwise did well. On cutting open the tumour it was found to be of a curious red colour, quite different from that of the ordinary whitish myoma. The tint varied from a brick-red to a dark mahogany-brown. The surface of the section was smooth and showed little trace of the fibrous structure of a myoma. Dr. L. Mackey has recently made a microscopic examination of a specimen for me and reports as follows: "The central portion of the tumour has undergone a degenerative change and consists of a red mucinoid fluid thick with the débris of the growth. The peripheral portion, though reddish, is firm and tough. The microscopic appearances show it to be a fibro-myoma. The fibrous tissue is hyaline and almost structureless. The muscle cells show very elongated rod-like nuclei. As the central cavity is approached the onset of a degenerative change is shown by the poorness of the staining of both fibrous tissue and muscle; but there is no sign of any inflammatory process. The débris in the cavity consists of fragments of fibrous and muscular tissue, the nuclei of which stand out from the more degenerated protoplasm. The fragments are œdematous, the lymph spaces being dilated. Mixed with the fragments is a good deal of old hæmorrhage and broken down red corpuscles. The condition appears to be that described as red degeneration and microscopically is a sort of necrosis without inflammation."

2. *Necrosis.*—We now come to the cases where necrosis or death of a fibroid occurs. It happens in about 4 per cent. of all myomata. When a cystic fibroid undergoes necrosis the fluid contents become converted into a kind of pus and then the growth is termed a suppurating fibroid. It is rare for an interstitial myoma to necrose, probably because it is well

supplied with blood on all sides. The submucous and polypoid varieties are, however, very prone to do so.

Let us consider how the necrosis is brought about. A myoma is nourished almost entirely by its vascular capsule, the growth itself being practically free from blood-vessels. The growth tends to become more and more submucous and is finally covered on the inner aspect by mucous membrane only. The uterine contractions try to force the fibroid through the cervix, just as in labour the fœtal head is driven down. The patch of mucous membrane, gripped by the cervical ring, becomes devitalised and sloughs, laying bare the myoma proper. This is now nourished on its outer aspect *only, and imperfectly there. Germs get access* to it from the vagina and complete the work of destruction. The tumour dies, becomes greenish grey or blackish grey in colour, and breaks down into a horribly offensive, soft, mushy mass, which is slowly extruded through the cervix.

There are other modes by which a submucous myoma may become infected and necrose: (*a*) by the passage of a dirty sound in examining the uterus; (*b*) by an intra-uterine operation, such as curetting, done with dirty hands or instruments; or (*c*) by the puncture of the growth with Apostoli's electrolytic needles (this was a fertile source of disaster when this method was in fashion). However *produced, when once* necrosis has set in, it is unmistakeable. The stench of these cases is sometimes appalling, filling the whole house. At the same time, the patient becomes infected and poisoned by toxins absorbed from the gangrenous tumour; and, if not speedily relieved by operation, will die from septicæmia or pyæmia. In some of my most putrid cases, however, I have been amazed by the absence of any systemic infection, the patient being only distressed by the disgusting smell of her discharges. This, no doubt, must be explained by the slow onset of the process, allowing for self-immunisation.

These cases of sloughing fibroid may be mistaken *for* advanced cancer of the uterus—an error which would be disastrous if it led the surgeon to treat *the case as hopeless* and not attempt to remove the growth. It is not always easy to differentiate without a thorough examination under an anæsthetic. If the cervix be softened and dilated by a tumour being forced through it the tumour is a fibroid and not a cancer. If, beyond the necrosing part, a smooth rounded mass can be felt covered by mucous membrane it is probably a fibroid. If the protruding part be brittle and friable and crumble under the finger it is a *cancer.* A sloughing fibroid can be pulled away with forceps in stringy shreds or rounded masses, and on close investigation of these fragments some trace of the fibrous structure of a myoma may be seen. If still in doubt, a microscopic examination of a bit of débris will clear up the matter. It is of the utmost importance that a correct diagnosis be made, as an early operation will save the life of the patient if it be a fibroid; indeed, I know of no cases which *yield* more brilliant results to timely surgical interference.

3. *Malignant degeneration.*—The researches of modern pathologists and gynæcologists show that there is a marked tendency for a myoma to become directly transformed into a sarcoma. Winter examined microscopically 500 myomata and found sarcomatous changes in 4 per cent. Martin found sarcomatous degeneration in 6 out of 205, Cullingworth in 1 out of 100, Scharlieb in 6 out of 100, Haultain in 2 out of 120, Hirst in 3 out of 189, and McDowel in 20 out of 1000 cases. In my own 380 abdominal sections for myoma I found sarcomatous changes in 9 cases. Adding these cases together we find it occurs in a little over 2 per cent. But this list includes only the sarcomata recognised as originating in myomata. Probably many other cases, thought to be primary sarcomata, have originated in unrecognised myomata. Hence I think that Winter's figures give the truer proportion, viz., 4 per cent.

There can be no doubt that the subjects of myoma are specially prone to develop cancer of the uterus. It is not a degeneration or transformation of the myoma *into* cancer, but an associated lesion. In my own practice I found in 380 operations for myoma 6 cases *complicated* with cancer (1·6 per cent.). Noble, in 4880 cases he collected, found cancer present in 2·8 per cent., whilst it was present in 4 per cent. of the cases he himself had operated on. Of these 1·4 per cent. were cancer of the cervix and 2·6 per cent. cancer of the body of the uterus. Now *it* must be remembered that cancer of the cervix is ten times more common in women generally than is cancer of the body. If, therefore, cancer occurs twice as often in the body as in the cervix of myomatous uteri, there must be something in myomata which predisposes to the development of corporeal cancer.

Relation to Pregnancy.

Myomata tend to cause sterility. Mann found that 55 per cent. of married women with fibroids never conceived. Amongst married women generally only 15 per cent. are sterile, so there is nearly four times more sterility in myomatous women than in other women. It is fortunate it is so, as there can be no doubt that the occurrence of pregnancy adds greatly to the dangers of myoma. A woman with a fibroid is safer single than married and a married woman with a fibroid is safer sterile than pregnant. Some authors, noting that myomatous women are often sterile, have suggested that sterility is a cause of myomata. They suppose that these women ardently long to have children and that their unsatisfied maternal desires keep up a congested condition of the uterus and in some mysterious way produce a myoma. I do not believe in transcendental pathology and I think these theorists put the cart before the horse. The myoma causes the sterility and not the sterility the myoma. It is, moreover, easy to understand how the presence of one or more fibroid nodules imbedded in the womb may stimulate its sensory nerves and awaken strong maternal passions.

Let us now consider the results of pregnancy in a myomatous uterus. Whilst some women with moderately large fibroids go through pregnancy and labour without a hitch it is usually a serious complication. If the tumour be submucous or interstitial the patient generally aborts about the fourth month and this is the best thing that could happen for her. I have seen several cases of severe uncontrollable vomiting in pregnant women with interstitial fibroids, due, I believe, to the inability of the uterus to expand with the growth of the pregnancy. In most of these cases abortion had to be artificially induced. When abortion occurs, *whether spontaneously or induced, there* are apt to be retention of placental tissue and alarming hæmorrhage from imperfect contraction of the uterus. Another risk is that, following an abortion a submucous myoma may necrose and be a source of sepsis. I have already referred to the special tendency of red degeneration to occur in pregnancy.

A fibroid may be so large that it may mechanically prevent the normal development of the pregnant uterus and necessitate surgical interference. Some years ago I had sent to me, by Dr. C. Davidson of Coventry, a patient with a huge myoma and also a five months pregnancy. She was in great distress, and there was no room, apparently, for any further growth of the pregnancy. So I opened her abdomen and removed the entire uterus.

In some cases the fibroid is impacted in the pelvis below the pregnancy in such a way that it is obvious the child cannot be born *per vias naturales.* Wherever situated a large fibroid adds greatly to the risks of a full-time labour. It may interfere with the contractions of the uterus and so delay delivery. It may, by *preventing contraction* after delivery, cause retention of the placenta or alarming hæmorrhage. As a result of *bruising or torsion* the growth may undergo necrosis and cause fatal sepsis. It will thus be seen that the combination of pregnancy with a *large* myoma is a grave one, full of danger for the patient and anxiety for the medical attendant. The mortality is great, as in many cases surgical aid is not called in till it is too late.

Summary of Risks.

Let me now briefly summarise the risks which a woman with a fibroid tumour runs. 1. More than half the patients suffer from severe hæmorrhage and chronic anæmia. 2. Many patients develop heart disease, phlebitis, thrombosis, and embolism. 3. Other patients get retention of urine, cystitis, pyelitis, and hydronephrosis. 4. In about one-third of the cases the ovaries and tubes become diseased. 5. In about one-fifth of the cases *some form of degeneration* occurs, ending in nearly 5 per cent. in necrosis of the growth. 4 per cent. develop sarcoma and another 4 per cent. cancer. 6. More than half the patients are sterile, but should pregnancy occur the dangers increase with the progress of the gestation.

Natural Cure of Fibroids.

There are three modes by which a "natural cure" of a myoma may take place: (1) a submucous fibroid may necrose and slough away, or it may be extruded through the cervix as a polypus, *and* drop off; (2) a myoma may participate in the involution of the puerperium and disappear; *or* (3) it may undergo atrophy at the menopause.

The first mode—by necrosis and sloughing away of the tumour—I have already discussed. Needless *to* say, its risks are much greater than those of the most formidable of the modern operations for fibroids. The gradual conversion of a submucous fibroid into a polypus, followed by its extrusion and separation *en masse*, does undoubtedly occur. But it is a long, tedious, and dangerous process, more likely to kill the patient than to cure her.

The second process of natural cure—viz., by its sharing in the involution of the uterus after delivery—is also uncertain, and is more apparent than real. Myomata are very sensitive to changes in their blood-supply. When pregnancy occurs the increased vascularity of the womb causes the tumours to take on active growth. They often become more mobile—due no doubt to the softening of the surrounding uterine wall. An interstitial fibroid seems sometimes to be converted into a subserous one, by being pushed outwards toward the peritoneum by the growing ovum. Should the patient pull safely through the pregnancy and labour, the blood-supply of the uterus rapidly diminishes. The tumour then shares in the process of involution, shrinks in size, and in some cases seems to disappear. This fortunate result is, however, by no means a certainty, and in many cases the tumour, so far from shrinking, takes on more active development. It is probable, as Dakin says, that very few fibroids are absorbed; but many degenerate, become inflamed, or undergo necrosis. Only a few months ago I had to operate on a lady who had a large subserous fibroid growing from the top of her uterus. She had been confined three months before, when the tumour was discovered by her medical attendant (Mr. J. A. L. Peirce of Langley). Instead of shrinking during the puerperium it took on active growth. I opened her abdomen and found a large cystic fibroid attached by a broad pedicle to the top of the fundus. I removed it by dividing the pedicle, saving the rest of the uterus.

Lastly, a natural cure may occur by the absorption and disappearance of a fibroid at the menopause. This phenomenon was at one time looked upon as almost a certainty. The woman was told that if only she would wait till the change of life the growth would disappear and all her troubles would be at an end. But a sad experience shows that these hopes are illusory. As a matter of fact, the presence of a fibroid delays the natural change of life, and instead of the hæmorrhages ceasing at 45 years of age they go on with increased vehemence until the patient is 50 years of age, or 55 years, or even older. Let me relate a case in point. In 1898 I was consulted by a lady, aged 46 years, who had a myoma about as large as a five-months pregnancy reaching to one inch below the umbilicus. It caused severe and irregular hæmorrhages but not much pain. I advised ergot and hydrastis, told her to spend the whole of each period in bed, and urged her to wait for the menopause. Well, she followed my advice faithfully for years. I saw her at intervals and encouraged her to persevere and to wait for nature's cure. But, like the mirage in the desert, it kept receding into the distance and mocking her hopes. Finally, last year I had to perform hysterectomy. The tumour had now grown well above the umbilicus whilst the repeated hæmorrhages had blanched the patient and reduced her vitality. Considering her weak state she made a good recovery from the operation, but I feel that by following my advice to wait for the climacteric she wasted many of the best years of her life.

Even if the hæmorrhage ceases, this only removes one of the many risks of the condition. It is just at this period that the most serious forms of degeneration are apt to supervene. Noble, in his study of 4880 cases, says that he is not acquainted with a single authentic case in which a fibroid has entirely disappeared at or after the menopause.

Realising, on the one hand, the manifold dangers of myomata—the pressure symptoms, the cardiac and renal complications, the risks of degeneration, necrosis and malignant disease—and, on the other hand, the safety and the certainty of cure offered by modern surgical operation, I hold that we are not now justified in advising a patient with a troublesome fibroid to wait for the menopause.

UNIVERSITY COLLEGE HOSPITAL.—The committee is issuing a special appeal on behalf of this charity in which it is stated that the hospital has been compelled recently to sell £4000 of its small available funded property in order to pay overdue accounts of 1907. Failing a substantial response it appears that some of the beds must be closed, which would be doubly regrettable in an institution which had been so recently and handsomely equipped. The annual income required is £19,000.

Oliver-Sharpey Lectures

ON THE

PRESENT CONDITION OF OUR KNOWLEDGE REGARDING THE FUNCTIONS OF THE SUPRARENAL CAPSULES.

Delivered before the Royal College of Physicians of London on April 7th and 9th, 1908,

By E. A. SCHÄFER, LL.D. ABERD., Sc.D. DUB., F.R.S.,

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF EDINBURGH.

LECTURE II.[1]

Delivered on April 9th.

GENTLEMEN,—We may now return to the results of the investigations made by Dr. Oliver and myself during the winter of 1893-94. The first point established was the *punctum saliens* of suprarenal activity—namely, that intravenous injection of the merest trace of suprarenal extract is capable of producing a striking rise of blood pressure; while with larger doses the rise may be so great as to be beyond the registering power of a mercurial manometer of ordinary length, the mercury being driven out from the open end of the manometer tube. We found this rise of blood pressure to be due to two causes—namely, (1) contraction of arterioles; and (2) increased rate and energy of heart beat. We further noticed that sometimes in the early stages of action of the extract the heart, instead of being augmented and accelerated in its action, is strongly inhibited, so much so that the auricles may cease beating altogether, the circulation being maintained by the slow independent rhythm of the ventricles. When this happens two antagonistic influences are at work: the one, constriction of the arterioles, tending to raise the blood pressure; and the other, cardiac inhibition, tending to lower it. The former influence is, however, always the stronger, and if both vagi be cut, or if a small dose of atropine be given, the cardiac inhibition is no longer visible but is entirely replaced by acceleration and augmentation. This, of course, assists instead of impeding the effect of vaso-constriction, the result being that the blood pressure rises enormously. The cardiac inhibition is proved by this experiment (section of vagi or their paralysis by means of atropine) to be of central origin and due to the excitation of the cardio-inhibitory centre in the medulla oblongata by the extract. The moment the centre is cut off by section of the vagi, the accelerator influences, which are also put in action by the drug, take on their full activity. These influences act directly upon the heart itself. According to Neujean (1904) the action is also a central one; but, if so, it is completely obscured by the central cardio-inhibitory effect unless the vagi be first divided. The acceleration is very evident when the cord is cut and when all nervous connexions between the heart and the central nervous system are severed. It is never better exhibited than in the separated heart of the mammal fed through the coronary arteries with Ringer's solution, to which a minute amount of suprarenal extract or of its active principle has been added. It should, however, be stated that this particular form of demonstration of the fact under consideration was not possible at the time with which we are dealing, since the method of perfusion of the mammalian heart through the coronary arteries, which we owe to Langendorff, was not then accessible to us. Sometimes the inhibitory action is deferred, the accelerator influence being so strong as to eliminate it altogether for the time being. But after two or three minutes the inhibition may suddenly show itself and prevail for some time over the accelerator effect.

The result of the action of adrenin upon the heart is well shown if the contractions of the auricles and ventricles are separately recorded. It is then seen that the active substance acts mainly, so far as the inhibition is concerned, upon the auricles, which, when the action upon the inhibitory centre is powerful, may altogether cease for a time to beat, the ventricles continuing alone with an altered, slower, and somewhat irregular rhythm. Accelerator and augmentor effects, which are precisely similar to those which are obtained by electrical excitation of the sympathetic branches proceeding to the cardiac plexuses, are, on the other hand, produced upon both auricle and ventricle, each showing a striking increase in rate and force of beat. The effects obtained with the isolated frog ventricle fed by Ringer's solution were less striking than those got in mammals. There was only slight acceleration, but the beat, if weak, was strengthened, and if irregular became regular; and with larger dosage the systole was prolonged and the diastole reduced in amount, so that the heart remained almost completely contracted.

---

[1] Lecture I. was published in THE LANCET of May 30th, 1908, p. 1531.

One of the first points we set ourselves to determine was the question whether the vaso constriction which is so pronounced a feature of the action of the extracts is of central or of peripheral origin. This we investigated in two ways. First, we destroyed in the frog the whole of the central nervous system and having suspended the animal with the toes dependent we perfused Ringer's solution through the blood-vessels by means of a cannula tied into the aorta. The amount of fluid per minute flowing through the vessels and dripping from the toes was measured, and a small amount of suprarenal extract was then added to the fluid used for perfusion. We found that the addition of a little more than a trace of the extract produced so great a constriction of the arterioles that the flow of fluid nearly ceased. It was therefore clear that the constriction produced is independent of the central nervous system, and is probably of peripheral origin. Later, in the mammal, we adopted a somewhat different procedure. Having ascertained that section of the cord in the cervical region, whereby the vaso-motor centre in the medulla oblongata was cut off from the subordinate spinal centres, had no effect in abolishing the action of the extract upon the blood-vessels nor the raising of the blood pressure, we proceeded to try whether section of all the nerves passing to a limb would have any influence on its action upon the limb vessels. To test this we inserted both fore-limbs of a dog in plethysmographs, which were constructed like the original instrument employed by Mosso for the human arm, of glass cylinders; these communicated with recording tambours or piston recorders by rubber tubes filled with air. Under these circumstances, anything which would tend to constrict or dilate the arteries of the limb would produce a fall or rise, as the case might be, of the lever of the registering tambour. A blood-pressure curve was taken simultaneously in the same animal. To obviate the possible effects of muscular movements a small dose of curare was given, morphine being employed as an anæsthetic.

A first injection of saline extract of suprarenal produced the characteristic rise of blood pressure but not to an excessive degree. The register of both fore-limbs shows marked contraction; evidently the arterioles in both are undergoing constriction. This is not uniformly the case with the limb vessels, for they contract less readily than the vessels of the splanchnic area, and when the constriction of the latter is very marked the rise of blood pressure produced may even cause passive dilatation of the limb. The whole of the brachial plexus of the right fore-limb was now cut and the injection was repeated. The second curves under these altered conditions are so nearly identical with the first that unless they had been marked it would have been impossible to say which was the one taken before and which after section of the plexus. This experiment eliminates not only possible effects upon the centres for the blood-vessels in the medulla oblongata and spinal cord, but also any effects which might be caused by stimulation of sympathetic ganglion cells, for there are no known ganglia within the limbs. The inference, therefore, was obvious that the vaso-constrictor action is peripheral, and must be produced either upon the nerve fibres or upon their end mechanism, or upon the muscular tissue of the blood-vessels. Certain considerations led us to conclude that the effect was probably a direct one upon the muscular fibres, and although this conjecture was not at the time supported by convincing evidence it has since proved, as the result of experiments by others on the effect of the extract after section and degeneration of all nerve fibres, to be correct. This is a point to which I shall again have to return. Upon the respiration we found that the gland extracts had little immediate action, causing the rhythm to become at first more rapid and the depth shallower. These effects we found to pass off as the circulatory disturbance disappeared.

In the following winter (1894–95), Dr. Oliver being again set free from the cares of practice by the close of the Harrogate season, we resumed our joint investigation and extended it to other animals and to suprarenal glands obtained from various sources. These included the suprarenals from two cases of advanced Addison's disease which we found yielded no active principle at all. We determined that, although after each dose the effects are found to pass off within five or six minutes, if a saline solution containing suprarenal extract be allowed to pass slowly but continuously into a vein, the physiological effects which have been described, and especially the vaso-constriction and cardiac acceleration, are maintained during the whole period of flow. This has been confirmed by Crile and also by Kretschmer (1907). We investigated the effect upon other organs of the body than those previously tried and showed that both the spleen and kidney undergo a marked contraction under the influence of the extract; in the case of the latter organ with diminution of flow of urine. This is the more interesting because pituitary extract, which also produces well-marked contraction of blood-vessels and in some other respects similar physiological results to those caused by suprarenal extract, has an opposite effect upon the kidney vessels and urine, producing a dilatation of the renal arterioles and a free flow of urine. We also attempted to determine whether the extract has any effect on other glands and selected for this purpose the submaxillary of the dog. Having in one or two experiments, undertaken with this object, failed to obtain a flow of saliva as the result of administration of the extract we somewhat too hastily concluded that it had no effect upon these organs. Langley, however (1901), working with the cat, found that the extract produces from all the glands a flow of saliva similar to that which is yielded by stimulation of the cervical sympathetic. Our failure to observe this furnishes a lesson of the desirability of multiplying physiological experiments and of not restricting such observations to animals of one species. Had we been less easily satisfied with accepting our first negative results, which may have been due to an excess of the morphine which we used as an anæsthetic, we should not have missed so important an observation.

In the course of the previous investigations we had found that the extract not only produces a contraction or increase of tone in vascular and cardiac muscle but that frogs which had received a subcutaneous dose show an increased power of contraction of the skeletal muscles on stimulation of their nerves. In the further investigation (1894–95) we extended this observation to mammalian muscle and we further showed that this effect upon muscle lasts for some time after the effects upon the vascular system have disappeared. We therefore came to the conclusion that the active substance is probably taken up by, and remains for a time stored within, muscle and that this may in a measure account for its disappearance from the blood. For we at the same time determined that it is not excreted by the urine, nor is it at once reabsorbed by the capsules. In any case its ultimate disappearance is probably due to a process of oxidation occurring within the tissues. We showed that such oxidation does not occur in the blood, for a portion of the extract left in contact with arterial blood for 22 hours was just as active as a similar portion kept in saline solution. Kretschmer (1907) nevertheless believes that the disappearance of the effect is connected with the alkalinity of the blood, for he finds that if this is diminished by the administration of acids the effect of suprarenal upon the blood pressure is prolonged. According to Miller (1907) the active substance does not disappear from the blood. He states that the blood of a rabbit which has received a dose of adrenin will cause the typical rise of blood pressure if injected into another rabbit, although the effects upon the first animal may have disappeared. Finally, we proved that the extracts of the cortex of the gland are quite inactive, the active principle being confined strictly to the medulla. The principle is, in fact, now known to be identical or, at any rate, closely associated with the chromogenic substance obtained by Vulpian, which is contained in the chromophil or chromaffin cells of Stilling and Kohn.

During this same period (1894–95) and unaware of our experiments and observations of the previous winter, which were published in the *Journal of Physiology* in the spring of 1894 (the full communication appearing in the same journal in 1895), two Polish physiologists, Dr. Szymonowicz and Professor Cybulski of Cracow, were engaged upon a similar research. Their results were published as preliminary communications to the Academy of Sciences of Cracow in

February and March, 1895, and in full by Dr. Szymonowicz in *Pflüger's Archiv* in 1896. They observed many of the phenomena which we had described and brought independent corroboration of many of our observations. But in some minor details and in one important point they obtained different results. They were led to conclude that the extract produces its vaso-constrictor effects, not peripherally but centrally, upon the centres in the medulla oblongata, not upon the blood-vessels themselves. This was, as we have seen, obviously a mistaken conclusion, and it is difficult to understand how so experienced a physiologist as Professor Cybulski can have arrived at it. In most other points their results were corroborative of ours. They, however, referred the symptoms of Addison's disease partly to implication of sympathetic nerves and ganglia, partly to absence of the effects which, in conformity with the conclusions they had arrived at, are produced upon the nerve centres. To the Polish scientists must none the less be accorded the credit of having independently arrived at the establishment of the principle that the suprarenal glands are organs which yield an active internal secretion.

Recent Researches.

This was the condition of our knowledge of the subject in the spring of 1895. From this time onwards researches multiplied and many other interesting facts regarding the action of the extract were determined. One of these which has come to be of practical importance in medicine, and especially in surgery, was the proof of the direct local action of the extract. This was determined by Dr. Oliver (1897) who placed a fragment of dry medulla of a suprarenal capsule upon a small artery in the mesentery of a frog which was spread out under the microscope for the observation of the circulation. As the active material dissolved and penetrated to the walls of the vessel this showed a local contraction which became eventually so marked that the blood ceased to be driven through that particular artery. This suggested its applicability as a styptic and we came in the habit of employing it to check bleeding from wounds made in the course of vivisection experiments; its application to surgical needs of this description is now universal. Especially is it employed as an adjuvant to the subcutaneous injection of cocaine and similar local anæsthetics, the action of which it assists by diminishing blood flow and absorption in the part to be anæsthetised. In epistaxis I myself early had an opportunity of verifying its styptic character. And Dr. Oliver found that a congested and inflamed conjunctiva is at once rendered pallid under its influence. Similar but independent observations were made by W. H. Bates (1896), who published in the *New York Medical Journal* the result of its use in diseases of the eye. One of the most striking facts relative to this styptic action is that, although when given by the mouth, no evident change occurs in the blood pressure, there is very distinct evidence of vascular constriction, for bleeding from internal parts, such as the stomach, intestine, bladder, and uterus, even the bleeding of post-partum hæmorrhage, may thereby be effectually controlled. The explanation of this which most readily presents itself is that injured vessels are more susceptible to the extract and react to a slight excess of it in the blood more readily than do normal vessels. This is somewhat analogous to what is found after section and degeneration of the sympathetic nerve fibres to a part, in which case the reaction is also greatly intensified.

An enumeration of the various uses of the extract in clinical medicine and surgery has been given recently by J. L. Miller in the *Journal of the American Medical Association* for May, 1907. Amongst these he includes its employment as a topical application to mucous membranes, especially the nose and throat, and internally in a variety of different conditions, especially cardiac insufficiency, as in diphtheria—in which, as Elliott and Tuckett (1906) have shown, there is a deficiency of chromogen in the medulla—internal hæmorrhage, bronchial asthma, and the treatment of various transudates in the body cavities. Its use is indicated in cases where there are marked vaso-dilatation and insufficiency of cardiac action. Such conditions may be produced experimentally by chloral and some other anæsthetic drugs, and are present in the final stages of asphyxia. They also occur in shock. Gottlieb found that if the heart of a rabbit is brought to a standstill by chloral it may be revived by suprarenal extract, which is superior in its action to digitalis. Crile has shown its value in surgical shock, Miles and Muhlberg in vaso-motor failure from excess of ether; but in heart standstill from chloroform poisoning Dr. Herbert J. Scharlieb and I found it was impossible to revive permanently the cardiac muscle by adrenin. In conjunction with Dr. Herring I experienced a similar failure in asphyxia (from drowning) after both heart and respiration had ceased; although the heart may by its injection into the cardiac substance be stimulated to resume its action for a short time, the effect is not permanent. When the heart muscle is affected by disease, its value as a cardiac and vaso-motor stimulant is dubious, for it may throw too great a strain upon the weakened cardiac tissue. Thus, Gottlieb found that in a rabbit poisoned by repeated doses of diphtheria toxin, intravenous injections of adrenalin, although for a very short time apparently beneficial, were soon followed by still greater collapse and death. But probably administration by the mouth or subcutaneously, having a slower effect, might be beneficial in such cases. Kaplan and Miller both report satisfactory results from its use in bronchial asthma; it, however, only gives temporary relief and is in no sense curative. It is not known how the beneficial effect is produced; it is possibly due to inhibition of the bronchial musculature. Barr (1903) found that the fluid of pleurisy and other serous accumulations in the body cavities did not reaccumulate after evacuation and introduction of adrenalin.

In Addison's disease the employment of suprarenal extract has been found beneficial but not curative. This is scarcely to be wondered at when we consider that the primary cause of the disease is usually tuberculous or malignant affection of the capsules. The effect in diminishing the weakness and sense of lassitude is very marked in certain cases. In one of those reported by Langlois, in which prior to taking the extract the ergographic curve of the patient showed extreme muscular weakness and rapid fatigue, after a six weeks' course of the extract, the curve became as well marked and prolonged as that of a normal individual. In a few instances a cure has been reported, but this may occur without the use of the extract, and such cures of the diseases are probably due to functional suppression of the secretions and not to organic disease of the gland. O. Grünbaum (1907) states that suprarenal extract, although when administered by the mouth it ordinarily fails to show elevation of blood pressure, will produce this effect in cases of Addison's disease. Bossi (1907) reports great improvement in osteomalacia in pregnant women as the result of subcutaneous injections of the extract, but further experience is needed to confirm these observations. I need, however, not further dwell upon the clinical applications of suprarenal extract, which have, moreover, recently received adequate treatment from Rolleston in his address last year before the Canadian Medical Association. This would be occupying your time most unnecessarily, seeing that there is probably no one present in this room who is not better informed upon this subject than myself. It will be more profitable if I turn to the consideration of the data which have been added to our knowledge of the physiological action of the extract since the discovery of its best-marked effects.

The most important of these additional data were those contributed by Lewandowsky (1899), who found that the intravenous injection produces dilatation of the pupil, withdrawal of the membrana nictitans, protrusion of the globe, opening of the palpebral fissure, excitation of arrectores pili, and inhibition of the bladder. Boruttau (1899) showed that it causes inhibition of intestinal movements. All these results are also produced by sympathetic excitation. But that the effects are not the results of excitation of the sympathetic nerve fibres is clear from the fact, also discovered by Lewandowsky, that the results are equally well obtained after these fibres are cut and allowed to degenerate. Langley (1901–02) added to the list of sympathetic innervated parts excited by this substance the salivary and lacrymal glands, the liver, the muscular tissue of the uterus and vagina, of the vas deferens, and vesiculæ seminales, the dartos and the muscular coat of the stomach; in the last-named organ inhibition of the muscular movements is produced. On the other hand, the sweat glands are not excited to secrete, nor the pancreas, and the relative amount of effect produced is not the same as that caused by electrical stimulation of the sympathetic nerves to the part. Apocodeine abolishes the effects produced by sympathetic excitation and was found by Dixon to abolish those produced by adrenalin. He therefore concluded that this acts upon the endings of the sympathetic. But, as we have seen, Lewandowsky had shown that the effects are got after section and degeneration of the sympathetic fibres. Langendorff (1900), confirming older observations by Budge and others, found that the effect of agencies which produce pupil dilatation is enhanced after removal of the inferior cervical ganglion ("paradoxical effect"). Dr. and Miss Meltzer (1903) showed that this paradoxical effect is marked in the case of suprarenal extract; that after removal of the superior cervical ganglion the effect of intravenous injection, instead of disappearing within about a minute, becomes prolonged, and that subcutaneous injection and conjunctival application, which normally are without effect, now produce marked pupil dilatation. This observation was confirmed by Elliott (1904–05), who insisted upon the fact that the excitation must be due to some substance within the muscle fibres being affected by the extract, and suggested that this substance is present at the "myoneural junction," where it is originally formed under the influence of the sympathetic fibres. By an extension of this idea we can suppose that the formation being once started, its amount is also controlled by the sympathetic, and if this control be cut off an inordinate quantity may accumulate, thus increasing the excitability of the isolated muscle fibres. That the presence of nerve fibres is essential to the original appearance of such hypothetical excitable substance was shown by the observations of Macfie (1905), who found that the extract has no effect upon the movements of the protoplasm of amœboid cells or cilia nor upon the heart of the chick before the ingrowth of nerve fibres into it, although after such ingrowth the effect is most striking. Langley (1903–07) believes that the excitable substance which Elliott supposed to be confined to the myoneural junction is diffused through the protoplasm of the cell of which it has come to form an integral part. He proposes for the hypothetical material which thus reacts not only to adrenalin but in various ways to different drugs the name "receptive substance," and regards the differences of effect which he has determined in different sympathetic innervated organs as due to the relative amount of this substance in the cells. That there is some apparatus or material developed within cells originally under the influence of sympathetic nerves which is specially excited by adrenalin and by drugs of similar chemical character there can be no doubt, but whether it is limited to the region of the original nerve terminals or is diffused through the protoplasm is a point difficult of determination. It is not unlikely that experiments upon skeletal muscle, the excitability of which by various drugs is also affected by section of the nerves to the muscle, may throw light upon this question, which is one of great theoretical importance in connexion not only with the physiology of internal secretion but also with the action of drugs upon the muscular and glandular systems.

Another interesting datum which has been added to our knowledge of suprarenal extract is the observation that subcutaneous injection of adrenalin, even in relatively small doses (0·5 milligramme per kilogramme), produces marked glycosuria in both rabbits and dogs; the effect begins within one hour, and may last after a single dose for 24 hours or more. This was first noticed by Blum (1901), and the subject has since been followed up by various investigators, among whom may be enumerated Zuelzer (1901), Metzgar (1902), Herter (1902), Noël Paton (1903), and Lazarus (1907). The last observer states that after prolonged treatment with adrenalin there is marked hypertrophy of the islets of Langerhans of the pancreas, as well as of the suprarenals. There is, however, so much variation in the apparent amount of the islet tissue, even in the normal pancreas, that statements of this kind must be received with caution. Herter and Richards and also Paton showed that, as with phloridzin and pancreatic diabetes, glycosuria occurs even when stored carbohydrates have been previously eliminated. There undoubtedly seem to be connecting links between the glycosuria set up by pancreatic removal and that due to the action of suprarenal extract. Herter and Wakeman (1903) found that quite small amounts (1 cubic centimetre of a 1 in 1000 solution) of adrenalin applied to the pancreas provoke marked glycosuria. Intraperitoneal injection is more efficacious than subcutaneous. The amount of sugar in the blood is largely increased by the injection, while it is found to fall considerably on extirpation of the glands or ligature of the vessels. After such ligature removal of the pancreas may not produce glycosuria. Löwe (1907) found that in pancreas diabetes adrenalin readily produces pupil dilatation if dropped into the conjunctiva, whereas in the normal individual no such reaction is obtained. This observation was confirmed by Biedl and Offer (1907), and may serve as a diagnostic sign for this form of diabetes. Biedl (1898) had found that diabetes is produced by tying the thoracic duct, and even more effectually by leading it to the exterior and allowing the lymph to flow away, the amount of sugar appearing in the urine, even on a diet free from carbohydrate, being from 1 to more than 5 per cent. Biedl and Offer find that in this form of diabetes the pupil reacts readily to adrenalin dropped on the conjunctiva. They further find that admixture with lymph or simultaneous injection of lymph from another animal prevents adrenalin diabetes. The mydriatic effect is also said by them to be prevented by admixture with lymph, which, further, may be protein-free. Lépine (1890) had already noticed that in a dog with pancreas diabetes the injection of lymph from a normal animal produces marked temporary diminution of sugar in the urine. The idea which suggests itself is that the lymph normally contains a chemical (glycolytic) substance derived from the islets of the pancreas, which is essential to the due maintenance of normal carbohydrate metabolism.

We have seen that the most marked and probably the most important effect of suprarenal secretion in the body is to increase the contraction and maintain the tone of the blood-vessels. But the extract does not act equally upon all arteries. Its effect is perhaps greatest upon those of the splanchnic area; it is certainly less upon the arteries of the limbs, which may even be passively expanded in consequence of the great rise of pressure produced by contraction of the arterioles of the splanchnic area, this rise of pressure being assisted by the accompanying augmentation and acceleration of the heart. For the same reason the larger arteries, especially the aorta and its immediate branches, may stretch almost to rupture. Nevertheless, transverse strips of the muscular coat of the blood-vessels immersed in Ringer's solution containing suprarenal extract contract strongly, as do isolated sections of the vessels connected with a manometer and immersed in suprarenal extract. Some vessels, however, show much less contraction than others. Brodie and Dixon (1906) were unable to obtain evidence of constriction of the pulmonary vessels on injection of suprarenal; it is also difficult to show any effect upon them on excitation of the sympathetic. It is true that Bradford and Dean (1894) thought they could demonstrate a slight independent effect on the pulmonary arterioles on stimulation of the cord, but the method they adopted is open to criticism. Plumier (1907) repeated Brodie and Dixon's experiment and using stronger doses of adrenalin succeeded in getting a positive result. It is, however, clear that the action is far less than upon the systemic vessels. It has therefore been judged dangerous to administer adrenalin—even by the mouth—in pulmonary hæmorrhage, because it is supposed to raise the systemic blood pressure without constricting the pulmonary vessels and thereby to increase the tendency to hæmoptysis. But administration by the mouth does not perceptibly raise the systemic blood pressure and nevertheless there is considerable clinical evidence that internal hæmorrhages, when not too profuse nor coming from large vessels, may be brought under control by its oral administration. I have already suggested that it may have a greater effect upon injured vessels, and this may also be true for small ruptured pulmonary vessels. For my own part, I see no physiological contra-indication for its use in assisting to arrest hæmoptysis—when the bleeding is derived from rupture of small vessels. And certainly the bronchial vessels should be quite amenable to its action, whatever opinion may be held about the pulmonary arterioles. On the cerebral vessels also, although various observers at first failed to obtain evidence of contraction, it has now been shown by Wiggens (1905) by the perfusion method that the extract may produce a vaso-constrictor effect, although to a less degree than with ordinary arteries. Whether it can be used beneficially in threatening cerebral hæmorrhage is a question for clinical experience to decide, but as with the analogous case of pulmonary hæmorrhage there is no physiological contra-indication if administered by the mouth.

There remains for consideration the coronary circulation. Are the coronary vessels constricted by suprarenal extract, or are they dilated, or is there no specific action? Nothing is definitely known regarding the innervation of these vessels. Roy and Adami (1892) thought they had some evidence that the vagi may produce vaso-constrictor and the sympathetic vaso-dilator effects on them. But they did not employ the perfusion method to determine the point and their evidence must be regarded as inconclusive. It has, indeed, been generally held that the coronary arteries are little, if at all, controlled by vaso-motors. Recently (1906) I myself endeavoured to solve this question with the aid of the perfusion method. For this purpose I collected and recorded by a specially-devised apparatus the amount of Ringer's solution passing through the coronary vessels per minute in the isolated mammalian heart and observed the effects upon the flow of stimulating the vagus and sympathetic nerves passing to the heart. The results I obtained did not justify the inference that there exist active vaso-motor fibres, although I obtained during the cardiac acceleration, which was produced by stimulation of the sympathetic and still more during that produced by suprarenal, an increased flow of blood through the coronary vessels. This might, however, quite well be accounted for by increase in activity of the cardiac muscle, which would mechanically facilitate the flow through the coronary vessels. Langendorff (1907) has lately adopted another method for determining this question—namely, that of immersing strips of the vascular wall attached to a lever in adrenalin solution. He states that whereas strips from other arteries so tested contract when adrenalin is brought in contact with them, a strip from a coronary artery will become relaxed, and he infers from this that suprarenal extract produces inhibition and therefore vaso-dilatation. If this is so the action is different from that produced on all other vessels. Such a result would perhaps not be surprising, seeing that a rapidly and strongly contracting heart must necessarily pass more blood through its vessels than one beating slowly and less strongly, and suprarenal extract produces rapid and strong contractions. The subject is one which requires further examination, and, in fact, has been again studied in my laboratory by the method employed by Langendorff. Although not at the present moment prepared to make a definite pronouncement upon the question in all its aspects, I can, at any rate, state that we have never yet succeeded in obtaining the dilatation of a transverse strip of coronary artery (such as is represented by Langendorff) when pure suprarenal extract or adrenin unmixed with any other drug is added to the oxygenated Ringer solution, in which the strip of artery is immersed. It is, perhaps, possible that the contrary result obtained by Langendorff may have been due to the presence of some other substance than adrenin in the solution used by him. A pathological effect which has been noticed (Josué, 1903) as the result of repeated injections of adrenin into the auricular vein of the rabbit is a degenerated condition of the wall of the larger arteries, especially of the aorta (arterio-sclerosis). This effect is not peculiar to adrenin but is produced by other blood pressure-raising substances, such as digitalin and nicotine. The effect is seen also, according to Toropoff (1908), in the pulmonary artery. An account of these changes was given by Dr. H. Batty Shaw in his Goulstonian lectures in 1906, so that it is unnecessary for me to dwell further upon them.

CONCLUSION.
